SERIES

DEEP DIVE FOUR: **Decarbonization Impacts on Energy and Economic Equity**

Hosted by: Stephanie Waldhoff

Panelists: Brian O'Neill, Ying Zhang, Sumitrra Ganguli, and Stefan Rose

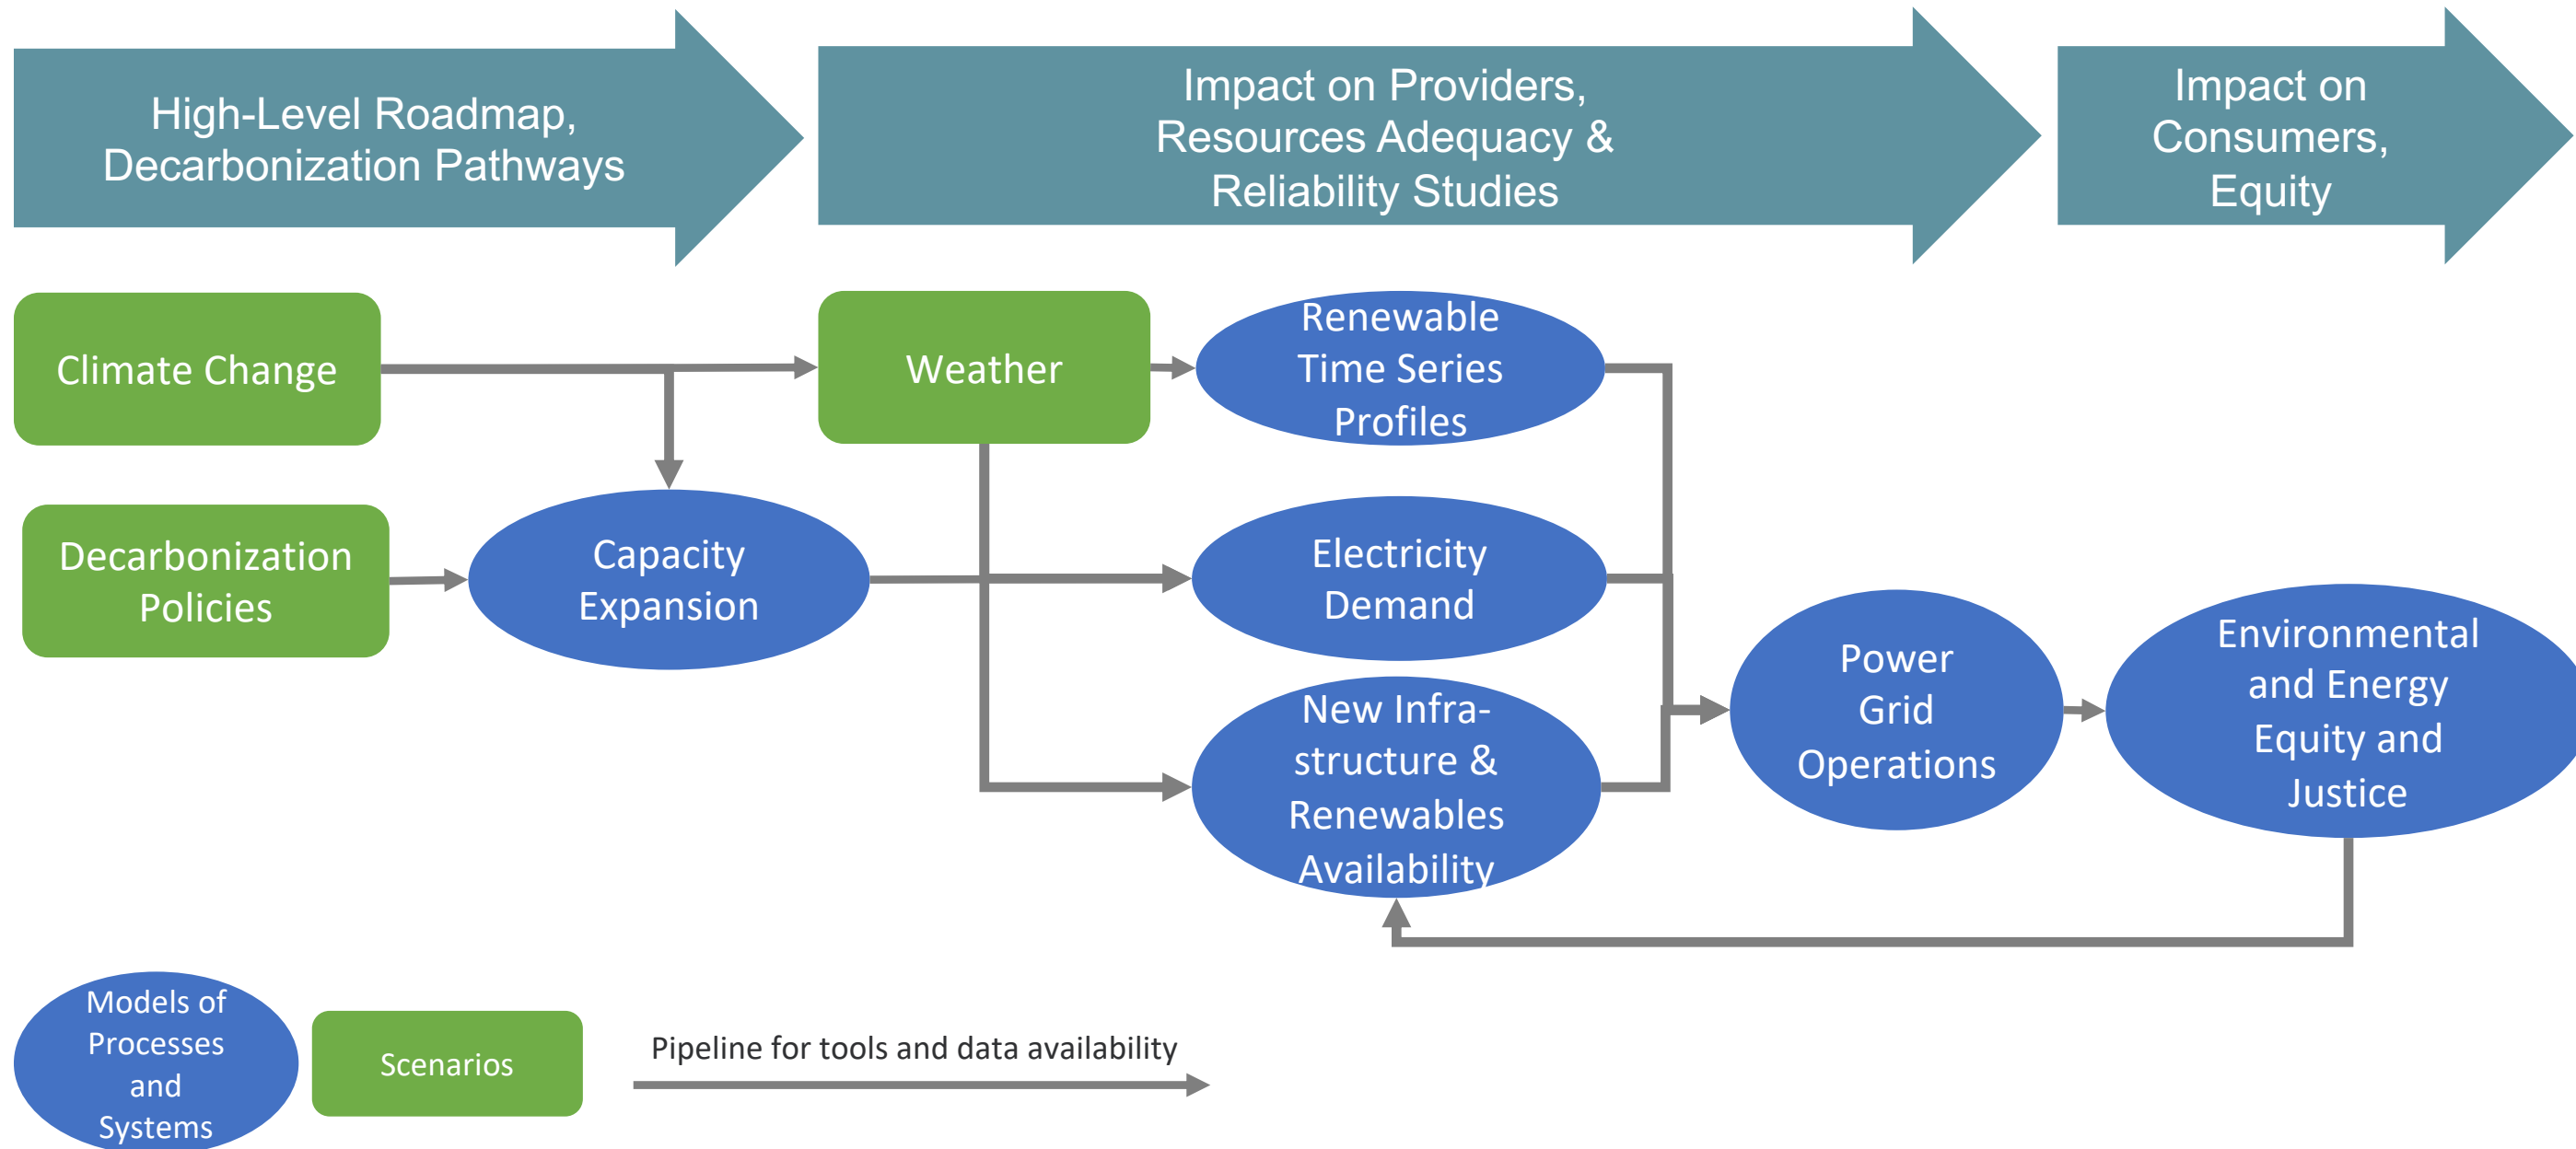

August 7, 2023

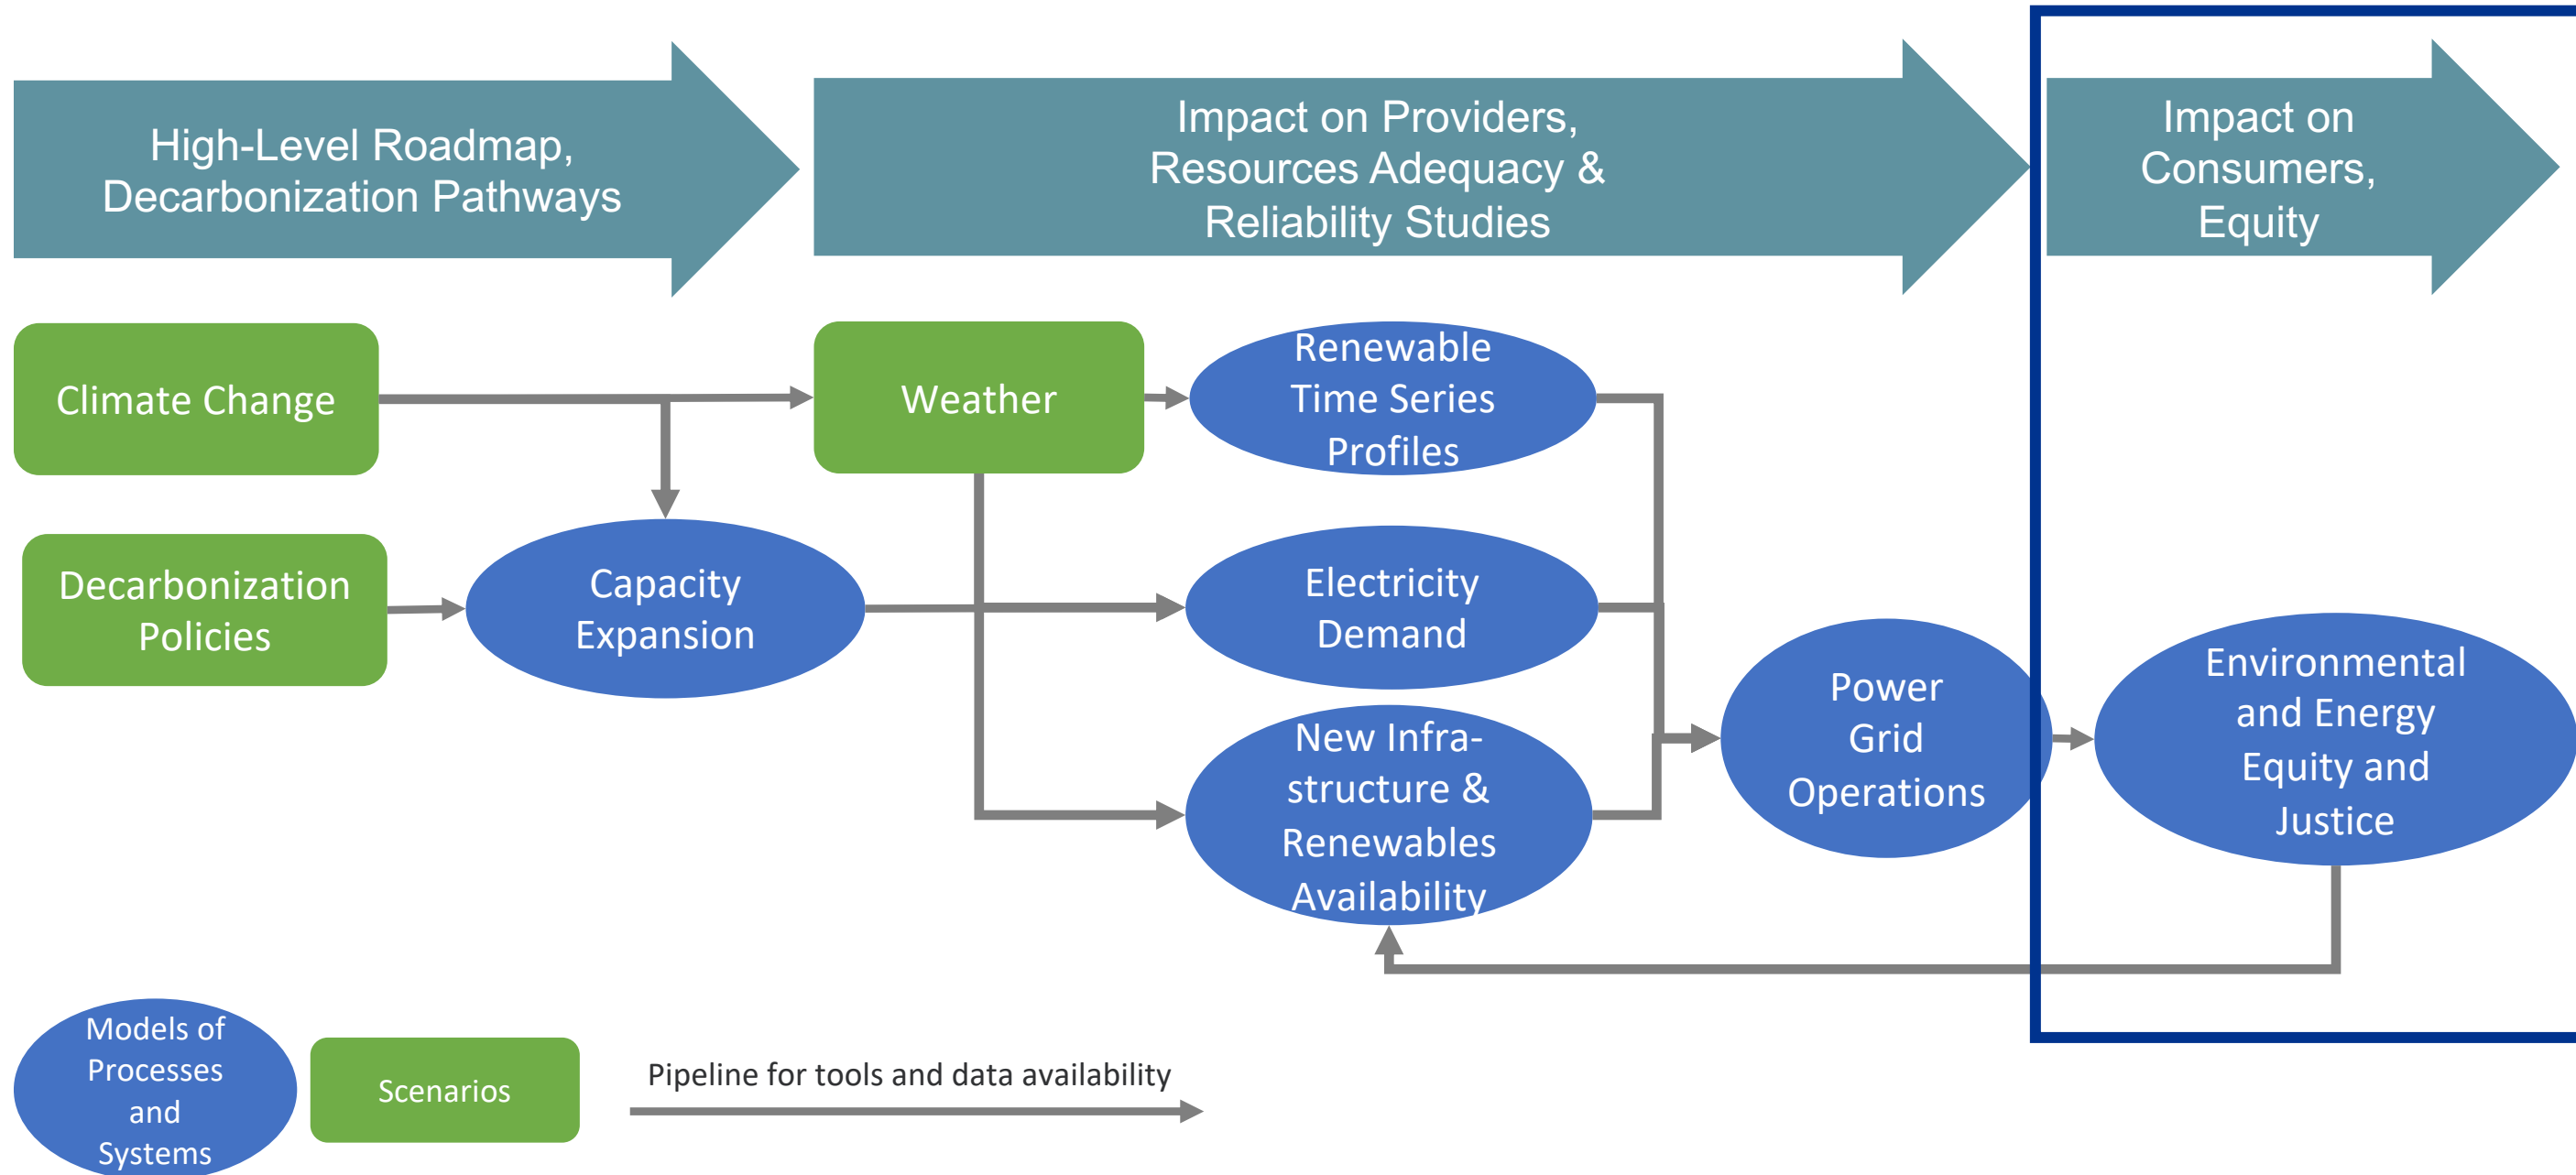

- How will consumers' energy security be impacted by a transition to a net-zero emissions economy?
- What types of jobs will be created or lost? Where will those jobs be located?
- What are the implications for consumers' incomes?
- How will disadvantaged communities be affected?

Visualizing and interacting with GODEEEP results

Satiation gap* in heating service: 2045, Decile 1
Under the Net Zero scenario, increases in electricity prices decrease heating consumption for the lowest income group

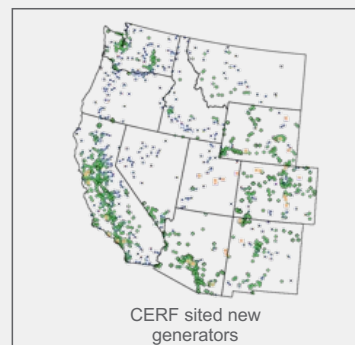

* Difference between heating consumption and the "ideal" heating or "satiation" level.

Employment and income changes in Washington State: 2035
Employment and income are impacted by both direct and indirect effects of decarbonization

Energy Justice-Visualization and Impact Analysis (EJ-VIA) tool

Multiscale

- Region
- State
- DAC census tracts
- Census block

Multi-metric

- Power plant emissions (CO₂, SO_x, NO_x, and PM_{2.5})
- Power plant capacity and locations (new, operational, and retired)
- Unserved energy
- Wholesale electricity costs

Please Note: At this time, data presented in the platform is illustrative only

Objectives and challenges

Objective: Define three 21st century socioeconomic scenarios that go beyond the current state-of-the-art in global change modeling to include projections for multiple income groups at the state scale in the United States.

Challenges:

- Projections of income distribution do not exist at the scale of U.S. states
- Currently available projections are primarily at the national scale
- New models and data development are needed

Jiang et al., 2020
(IM3 SFA)

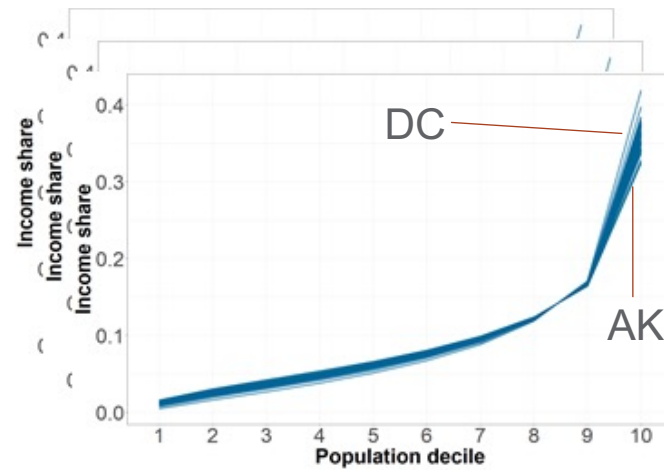

Dellink et al., 2017
DOE (EIA)

Requires:
Data:
Income, taxes
Model:
Changing
income shares

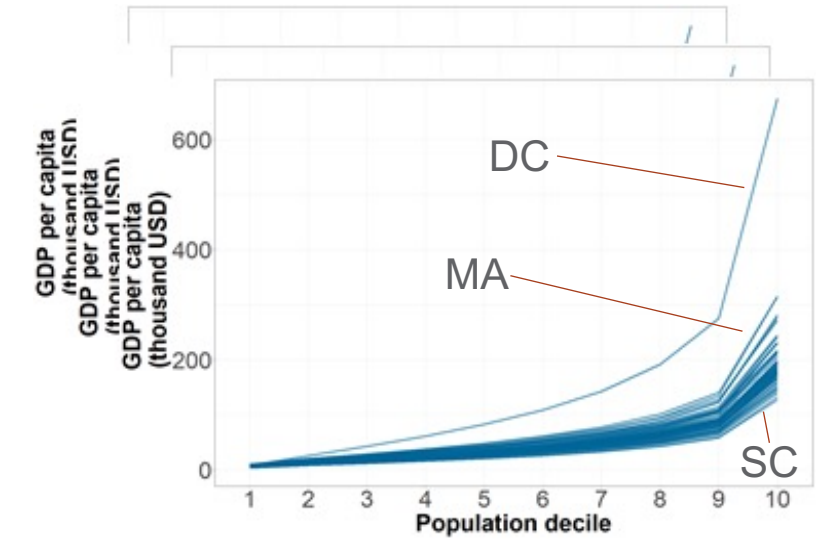

Deciles of income shares by state

Overall approach

Deciles of income by state

Income inequality metrics by state

Projection model

Non-parametric approach, fit to national data 1965-2015

Component weights projected by:

a -> Gini coefficient

b -> Labor share of income, lagged inequality

Base year data

American Community Survey (gross income by quintile)

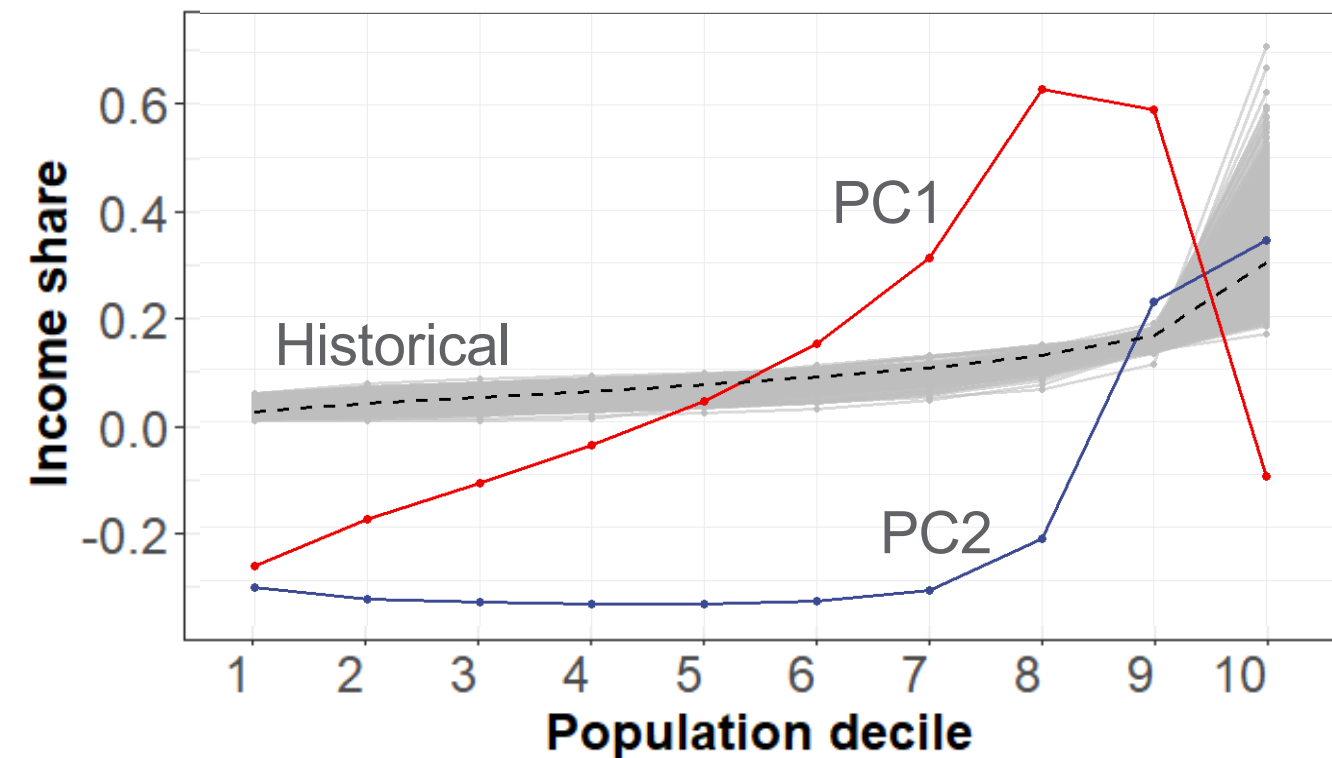

Congressional Budget Office (federal tax adjustment)

Brookings Institution (state tax adjustment)

Validation

Two principal components represent the data

$$\text{Income distribution (country, year)} = a * \text{PC1} + b * \text{PC2}$$

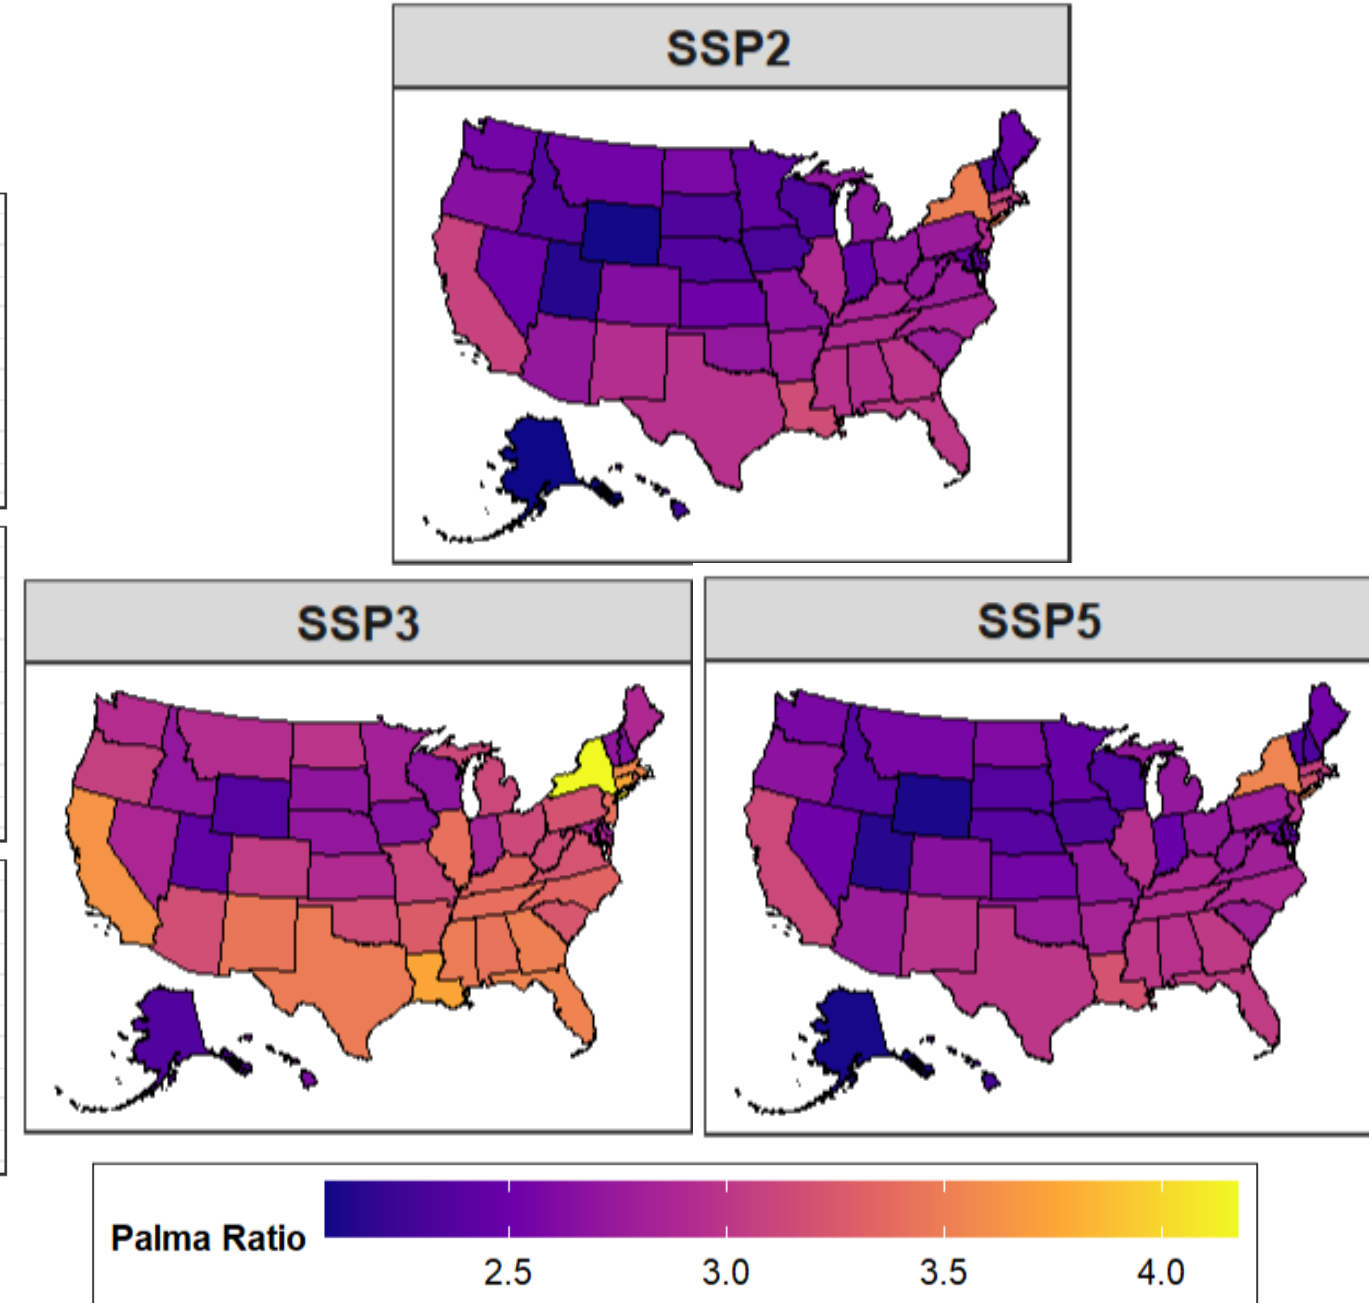

Results – 2050: variations across states and scenarios

Absolute income levels by state

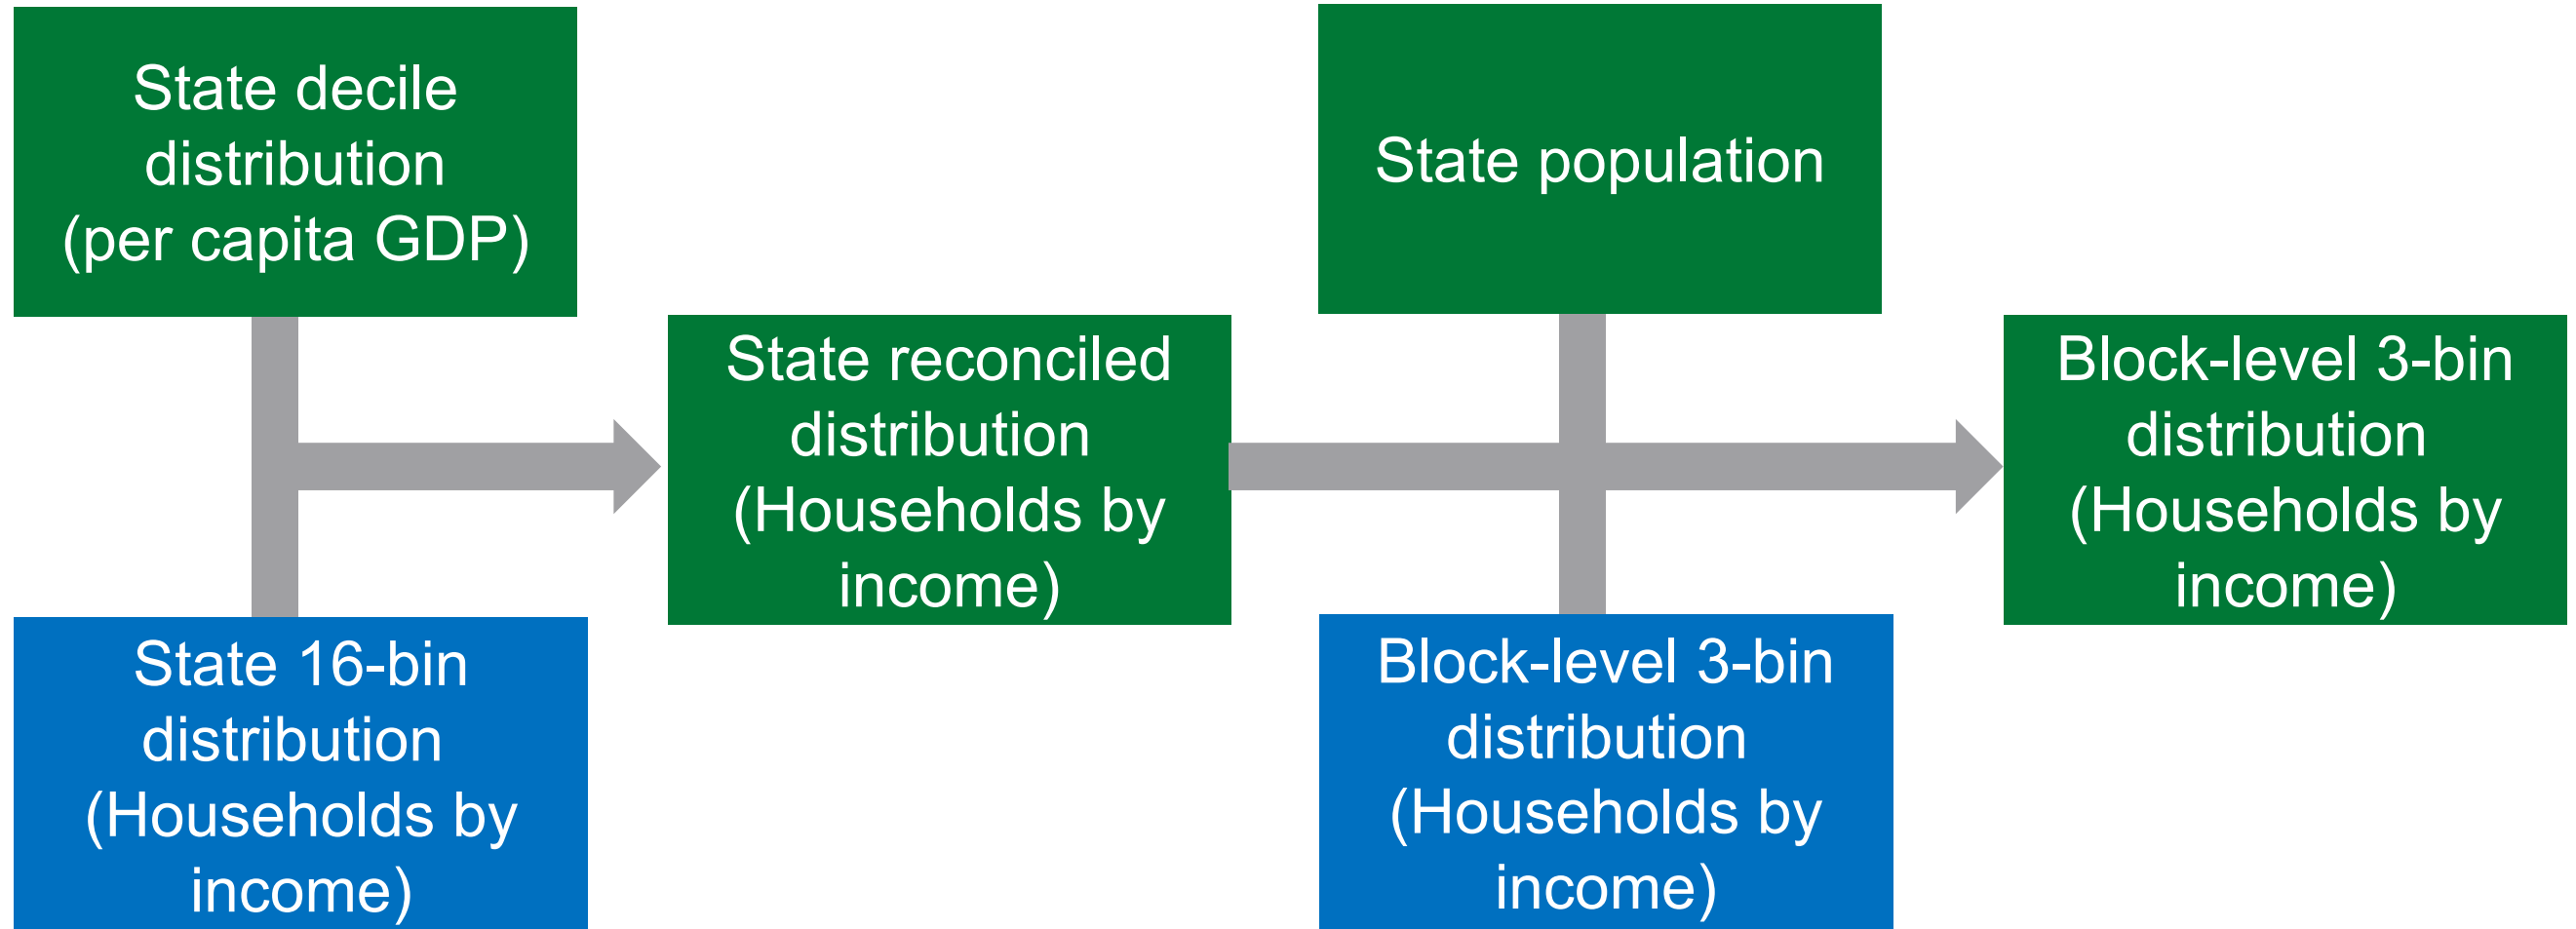

Metric of inequality
Palma Ratio (D10/(D1-4))

Projected income distribution, Washington – 2050

Downscaling Washington income distribution

 Projection

 Base year data

Downscaling Washington income distribution

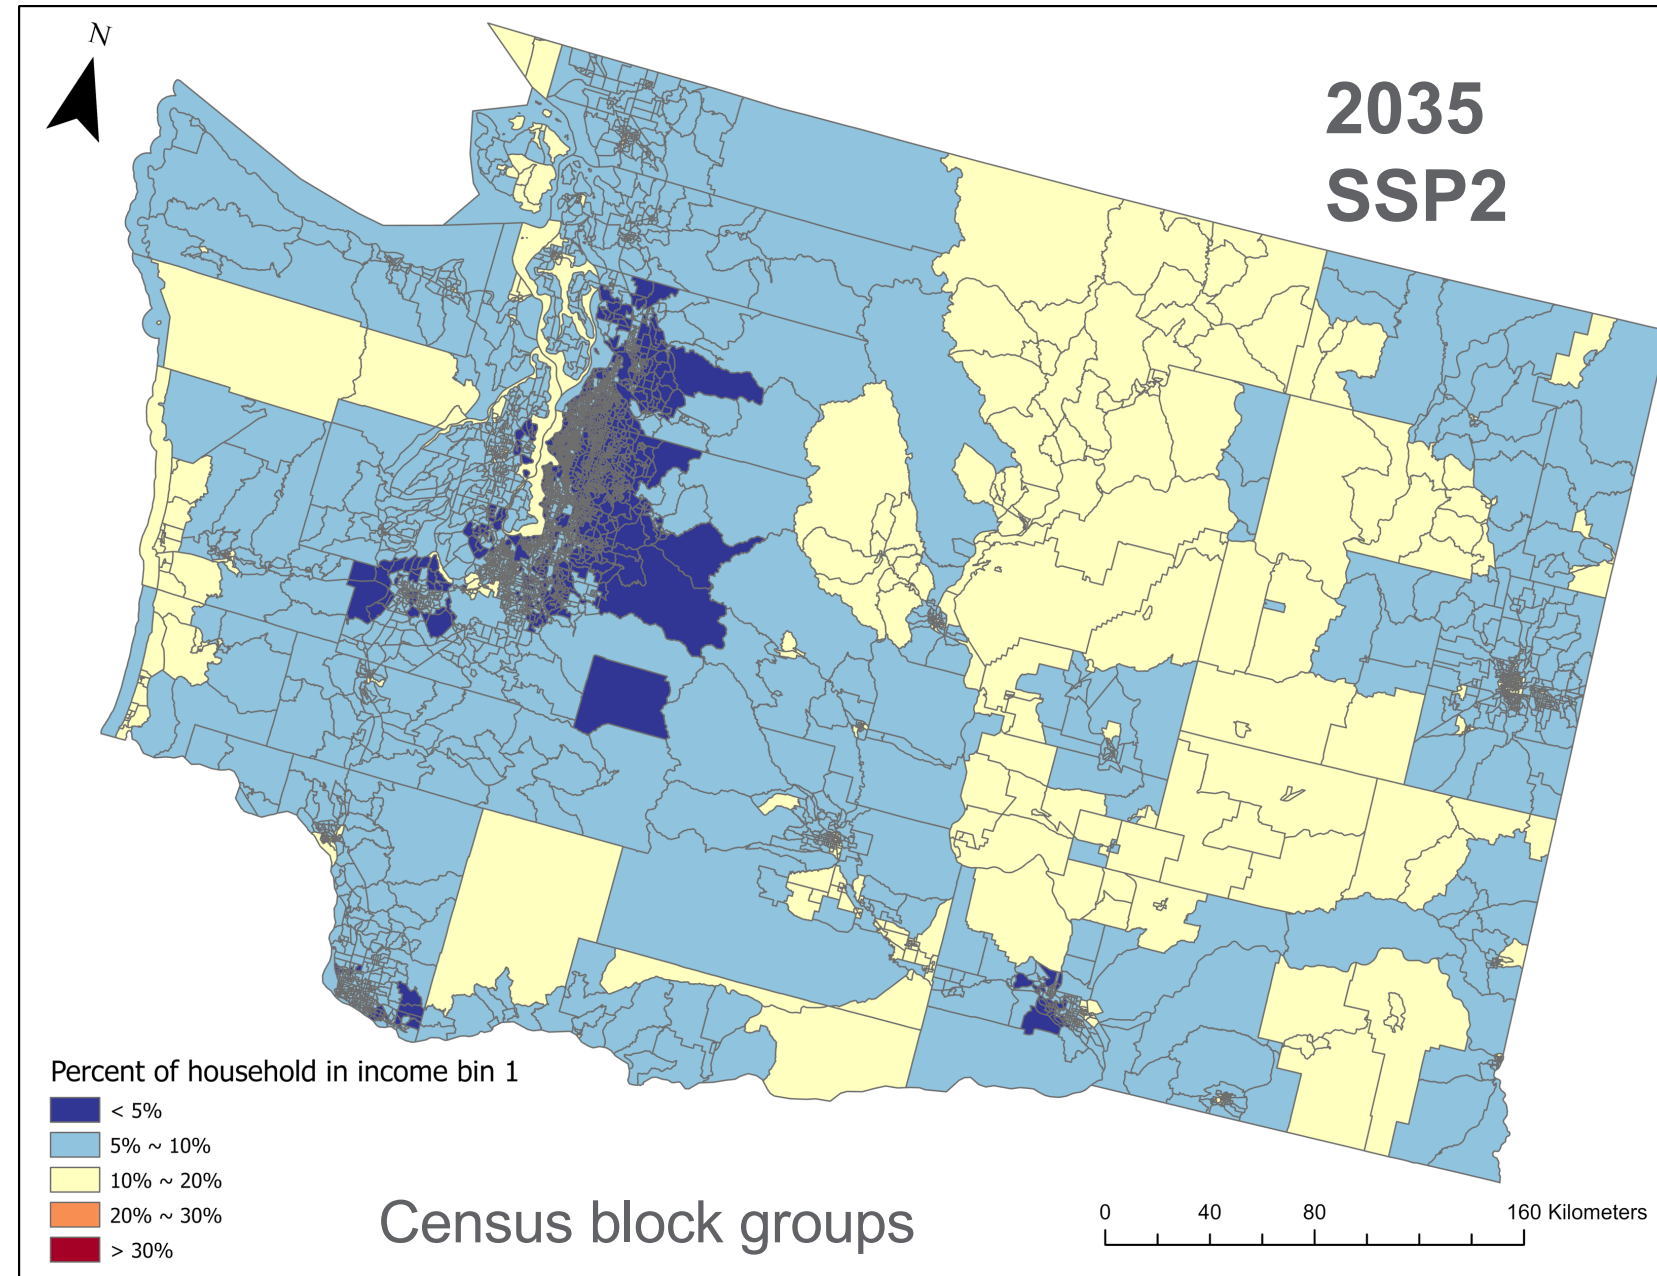

Percent of households in lowest income bin (<~\$18k/yr)

Downscaling Washington income distribution

Percent of households in lowest income bin (<~\$18k/yr)

Question and Answer

Residential energy security

Residential energy security

Residential energy security metrics

- Energy Service Consumption
 - Energy service received by consumers to meet their specific energy needs.
- Satiation Gap (a measure of comfort level)
 - Gap to which consumers feel that their energy needs are fully satisfied, and thus, they are no longer seeking additional energy services or improvements.
- Energy Burden
 - Percentage of household income that is spent on residential energy services.

Residential Energy Security

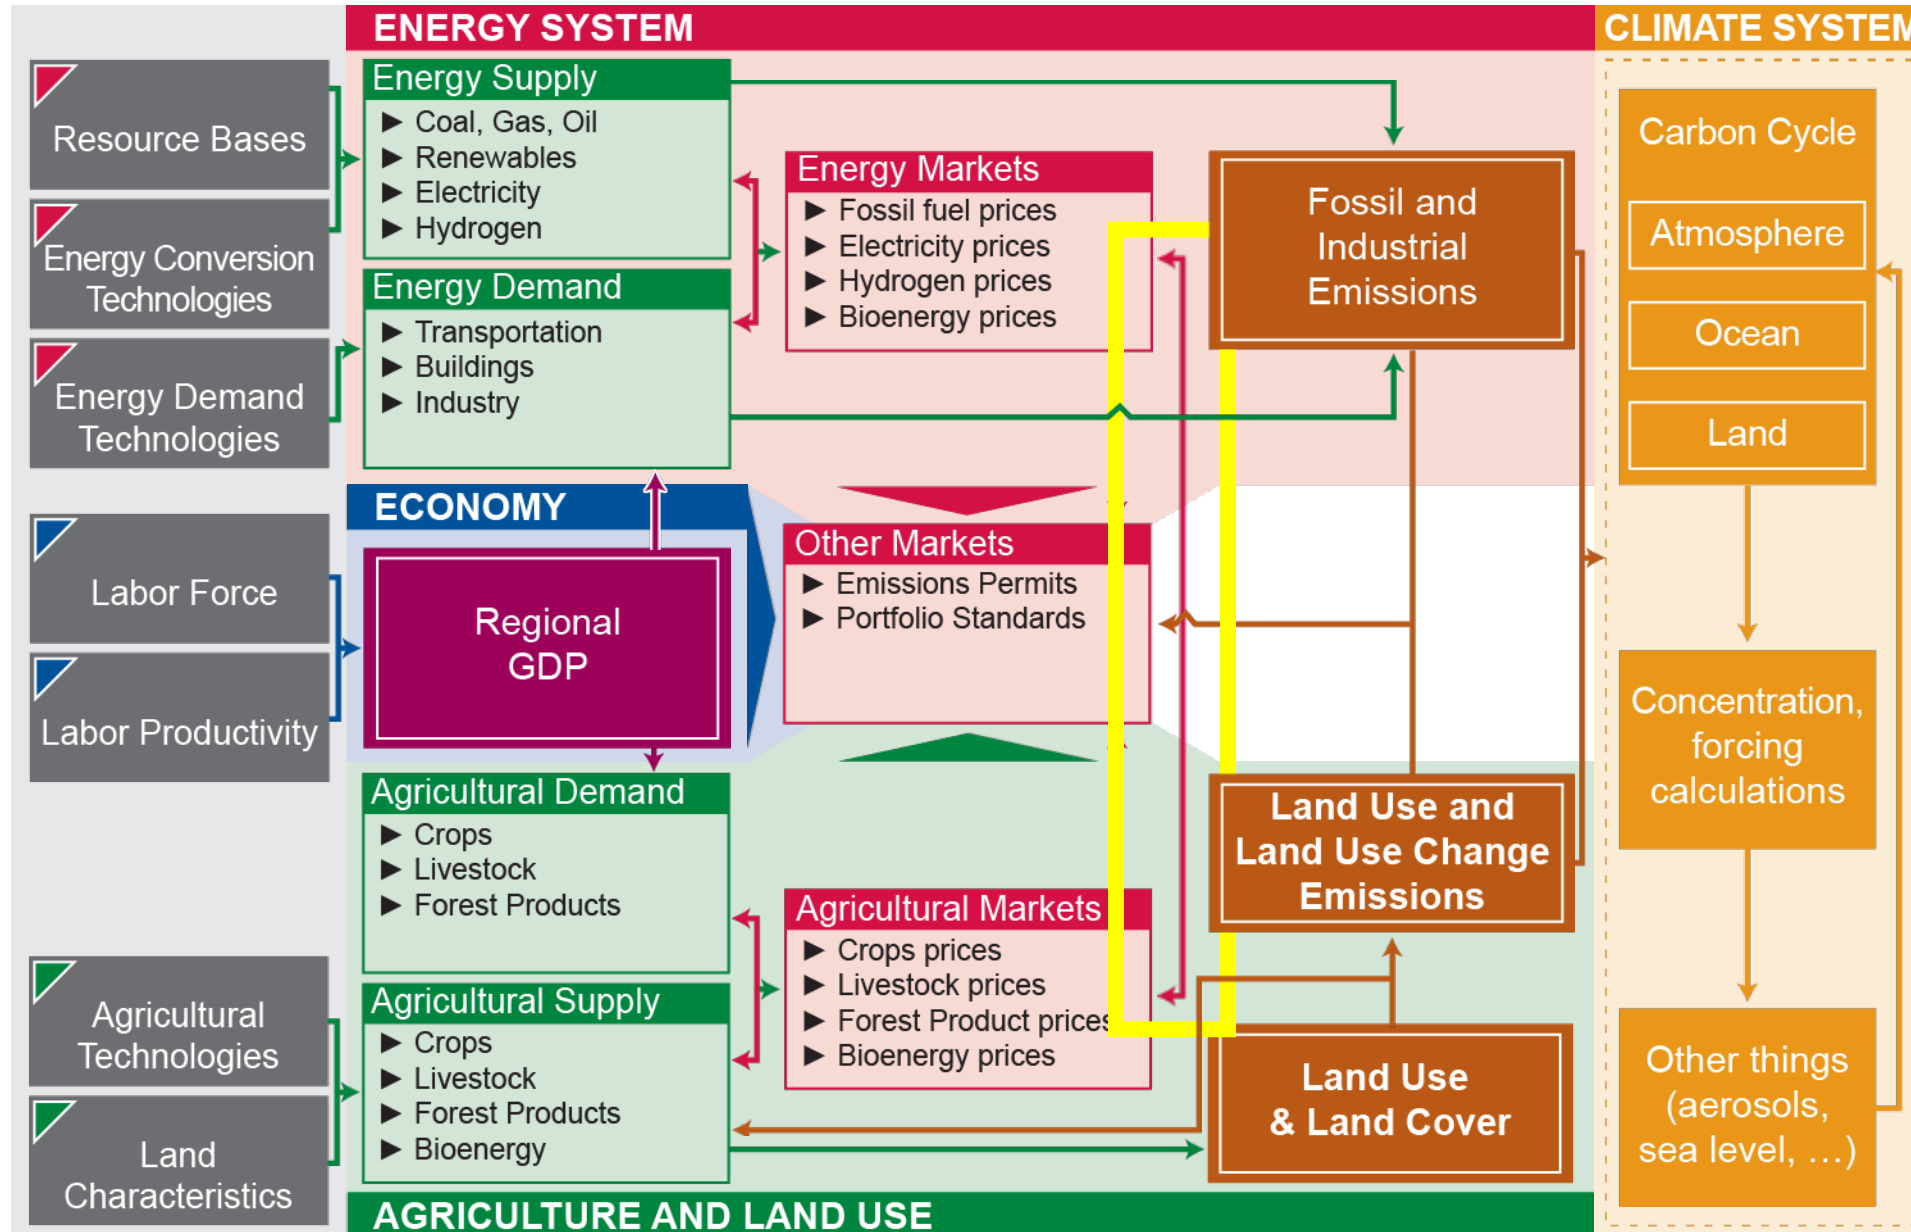

Acceptability Accessibility
Availability Affordability

“In 2020, 34 million U.S. households (27% of all U.S. households) reported difficulty paying energy bills or reported that they had kept their home at an unsafe temperature because of energy cost concerns.”

– U.S. EIA

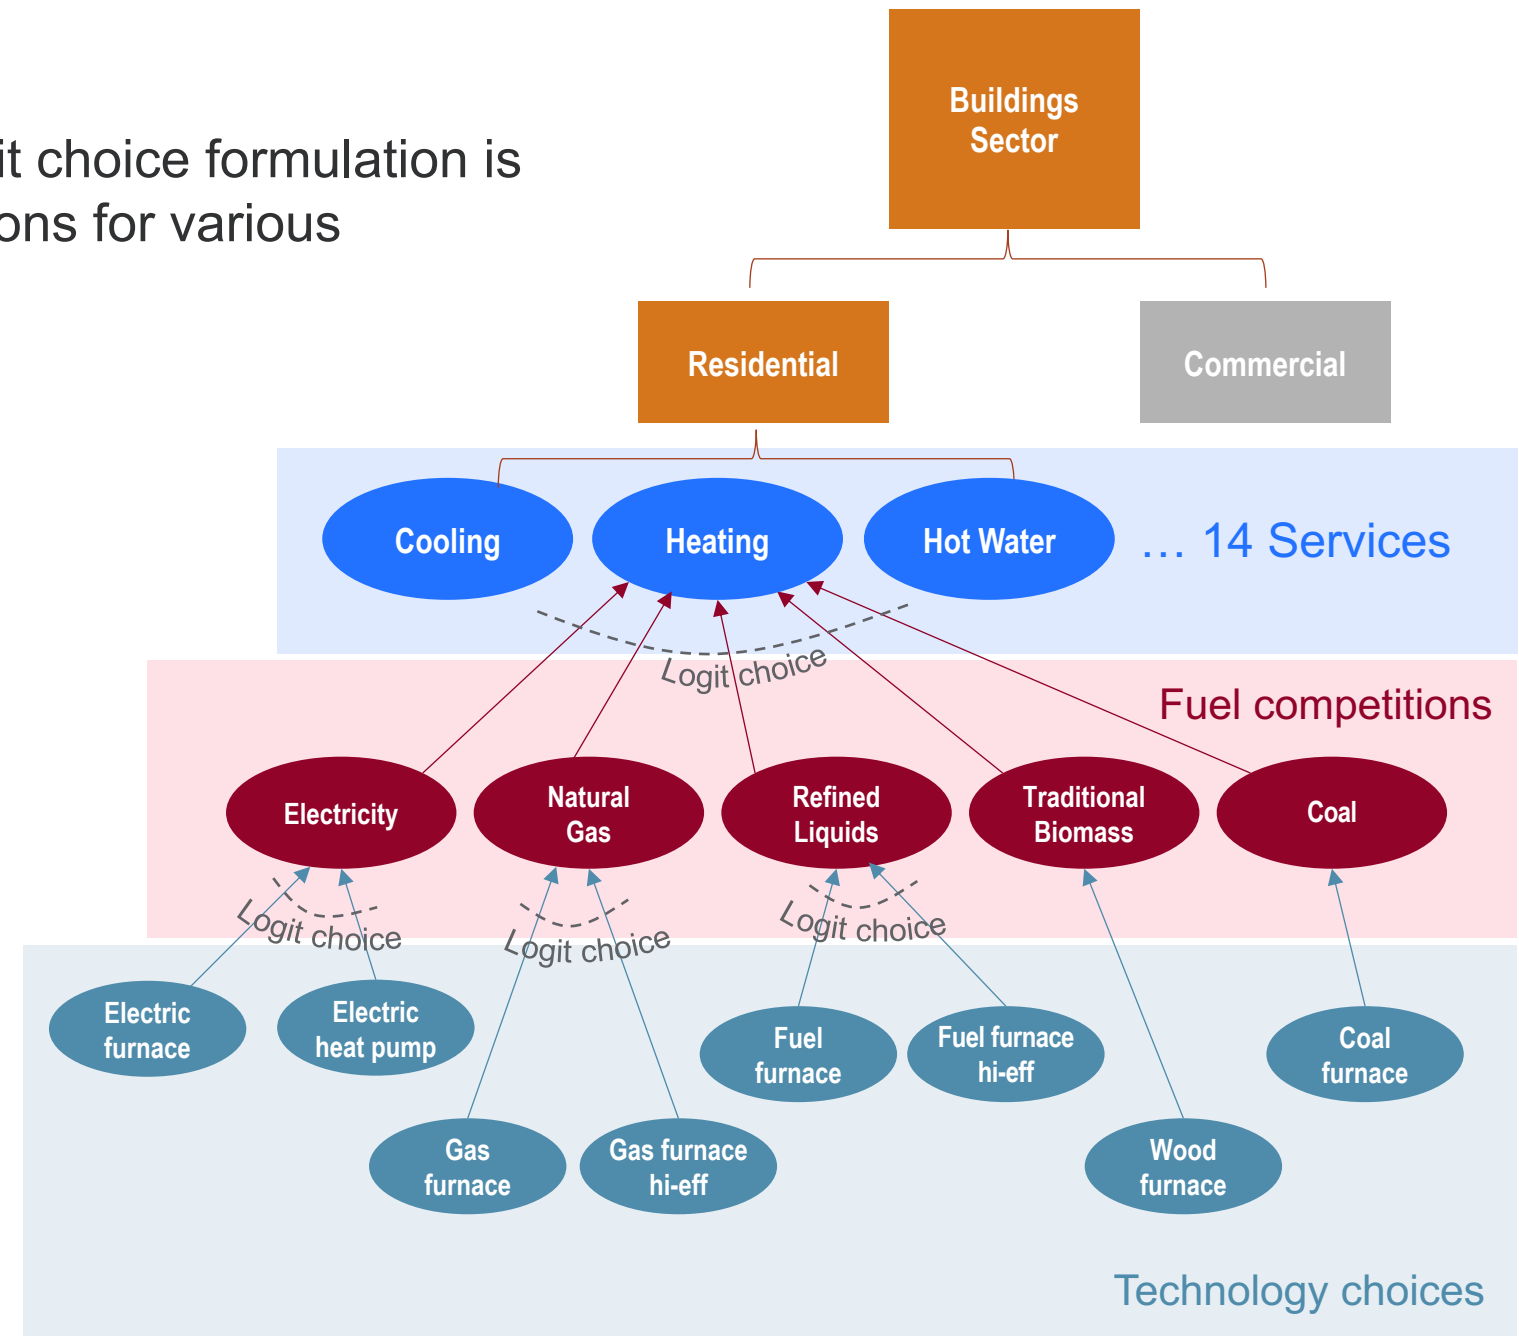

Global Change Analysis Model (GCAM)

- Open-source, well-documented **integrated multi-sector** model, which has evolved and expanded since the 1980s
- The model represents the behavior of and interactions between multiple systems/sectors
- Widely used to study **long-term** implications of various policy **scenarios** on global changes in the energy, land use, agriculture, water, and other related sectors
- **GCAM-USA** operates within GCAM with greater detail in the U.S.'s energy system

GCAM-USA's building sector

- In GCAM-USA, a nested structure based on logit choice formulation is used to represent fuel and technology competitions for various residential and commercial energy services.
- The future evolution of building energy use is shaped by changes in (1) floorspace, (2) the level of building service per unit of floorspace, and (3) fuel and technology choices by consumers.
- The energy consumption is calibrated in the historical period with of technology choice preferences captured in calibration parameters.
- Input assumptions of future technology costs, efficiencies, and lifetimes are based on the EIA Annual Energy Outlook (AEO) for baseline technologies.

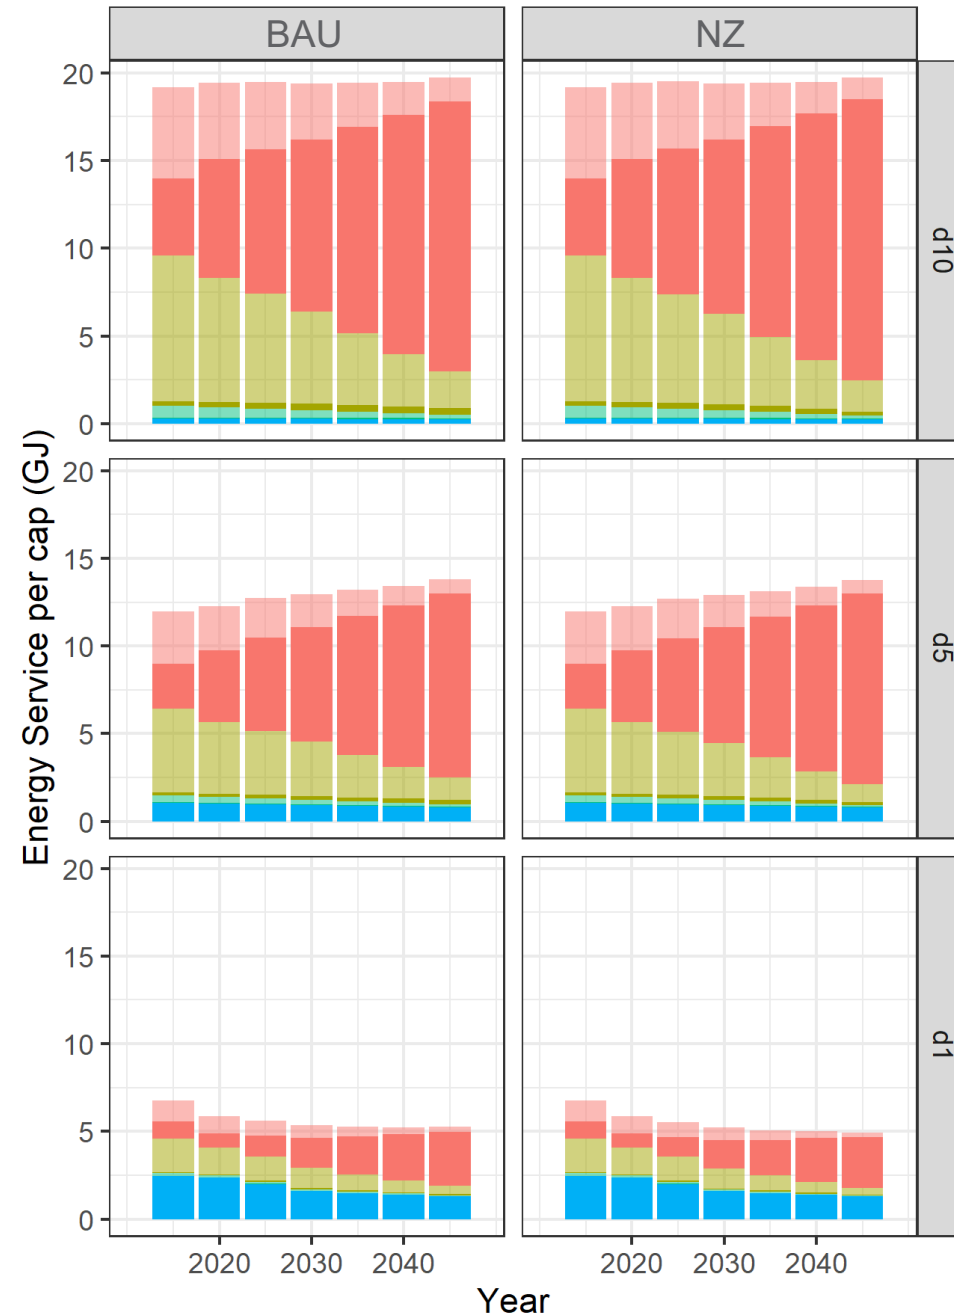

Residential heating service by technology in Washington State

d10
Highest income group

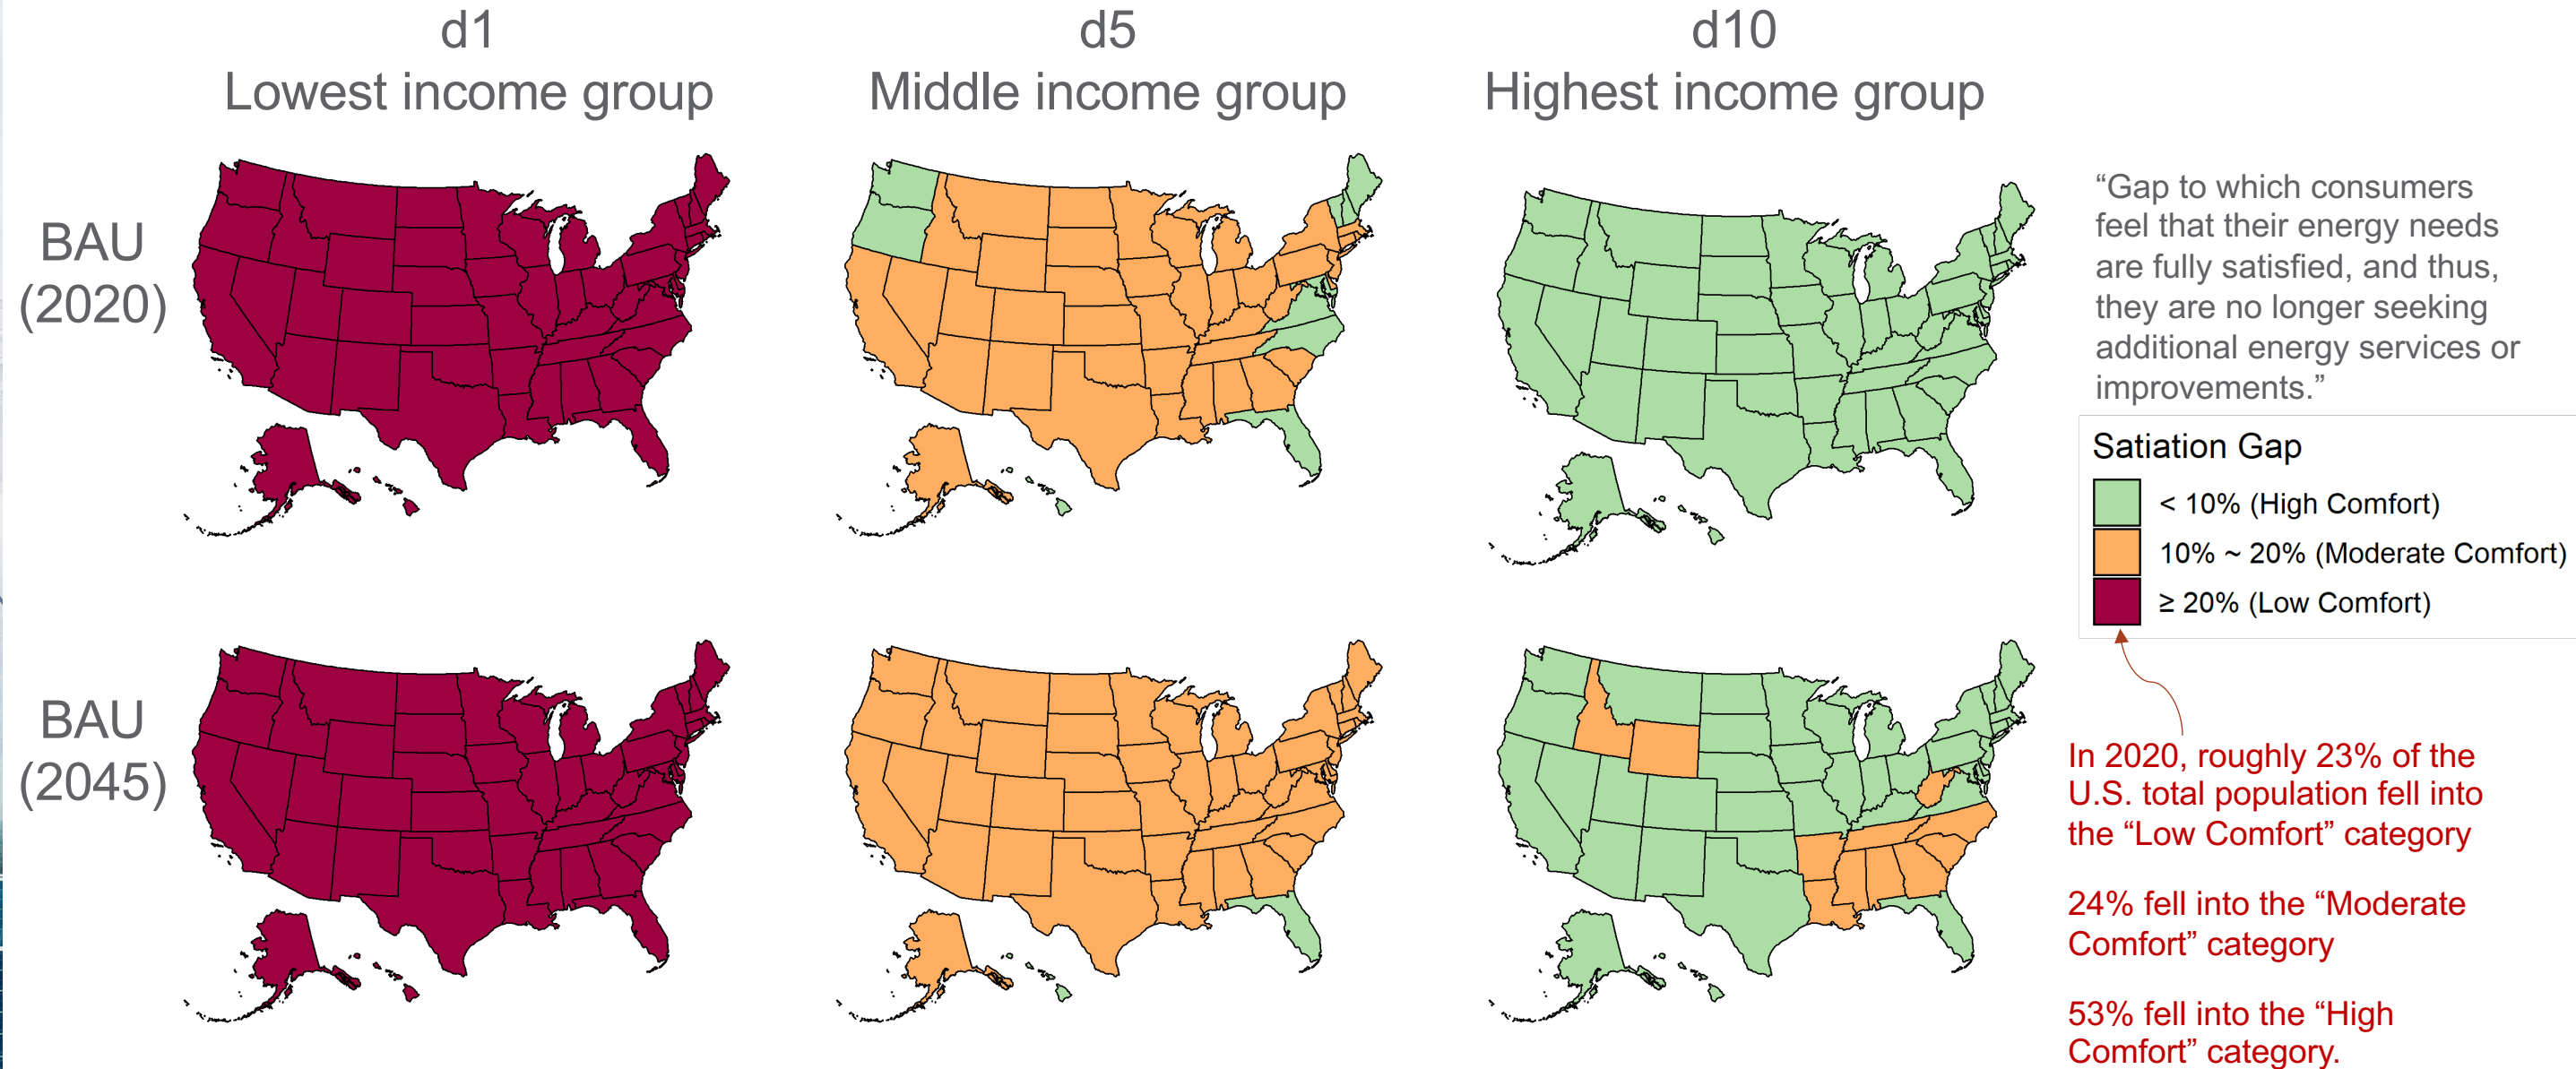

d5
Middle income group

d1
Lowest income group

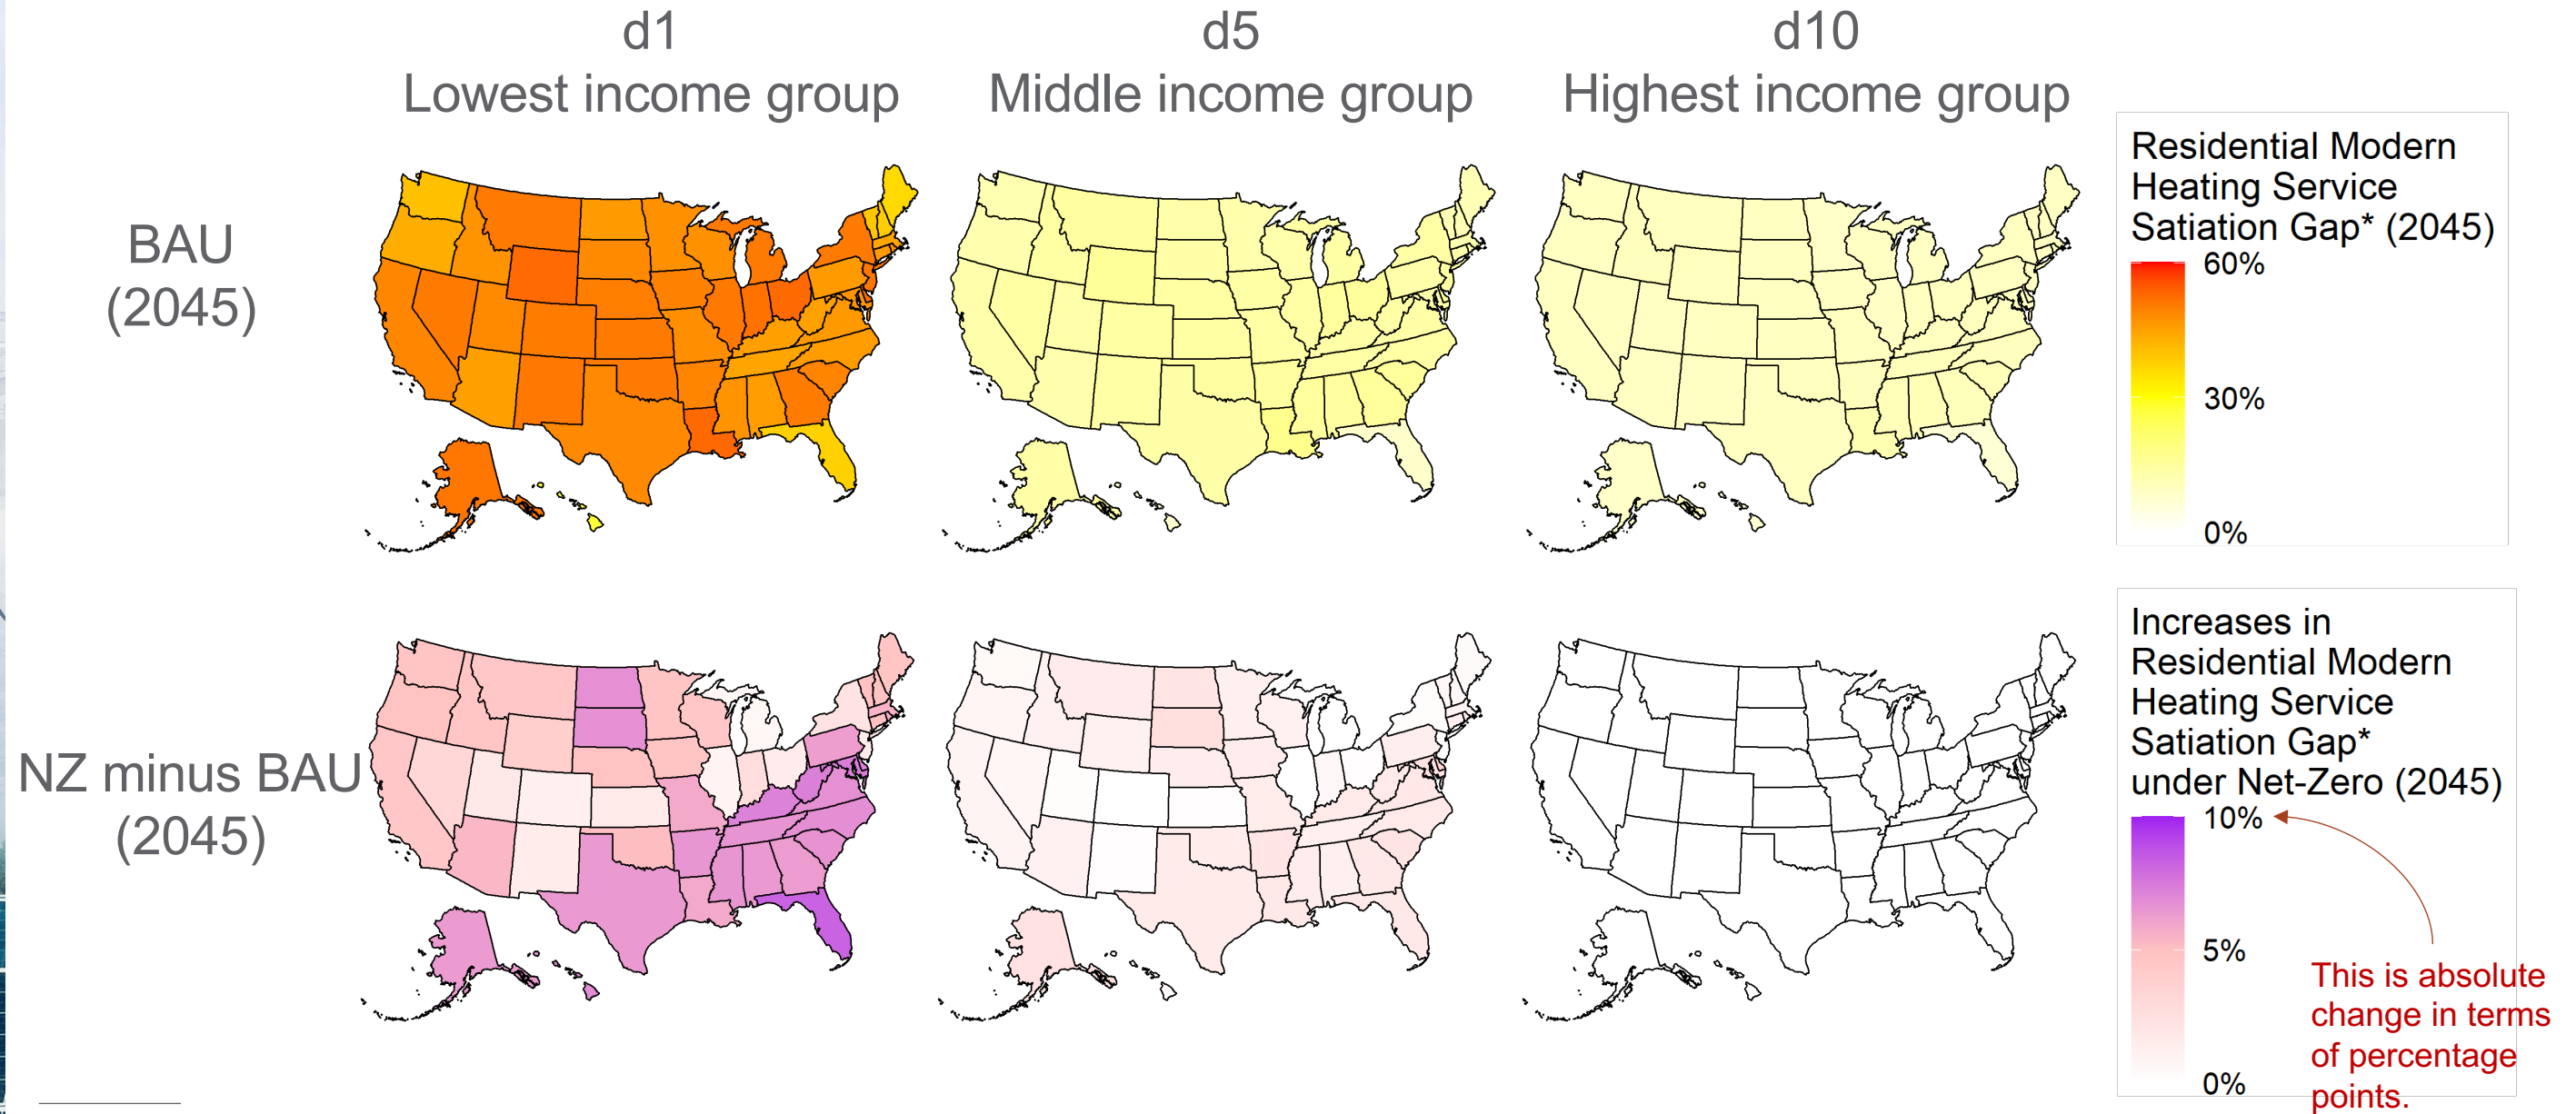

Satiation gap of residential modern heating service under business as usual

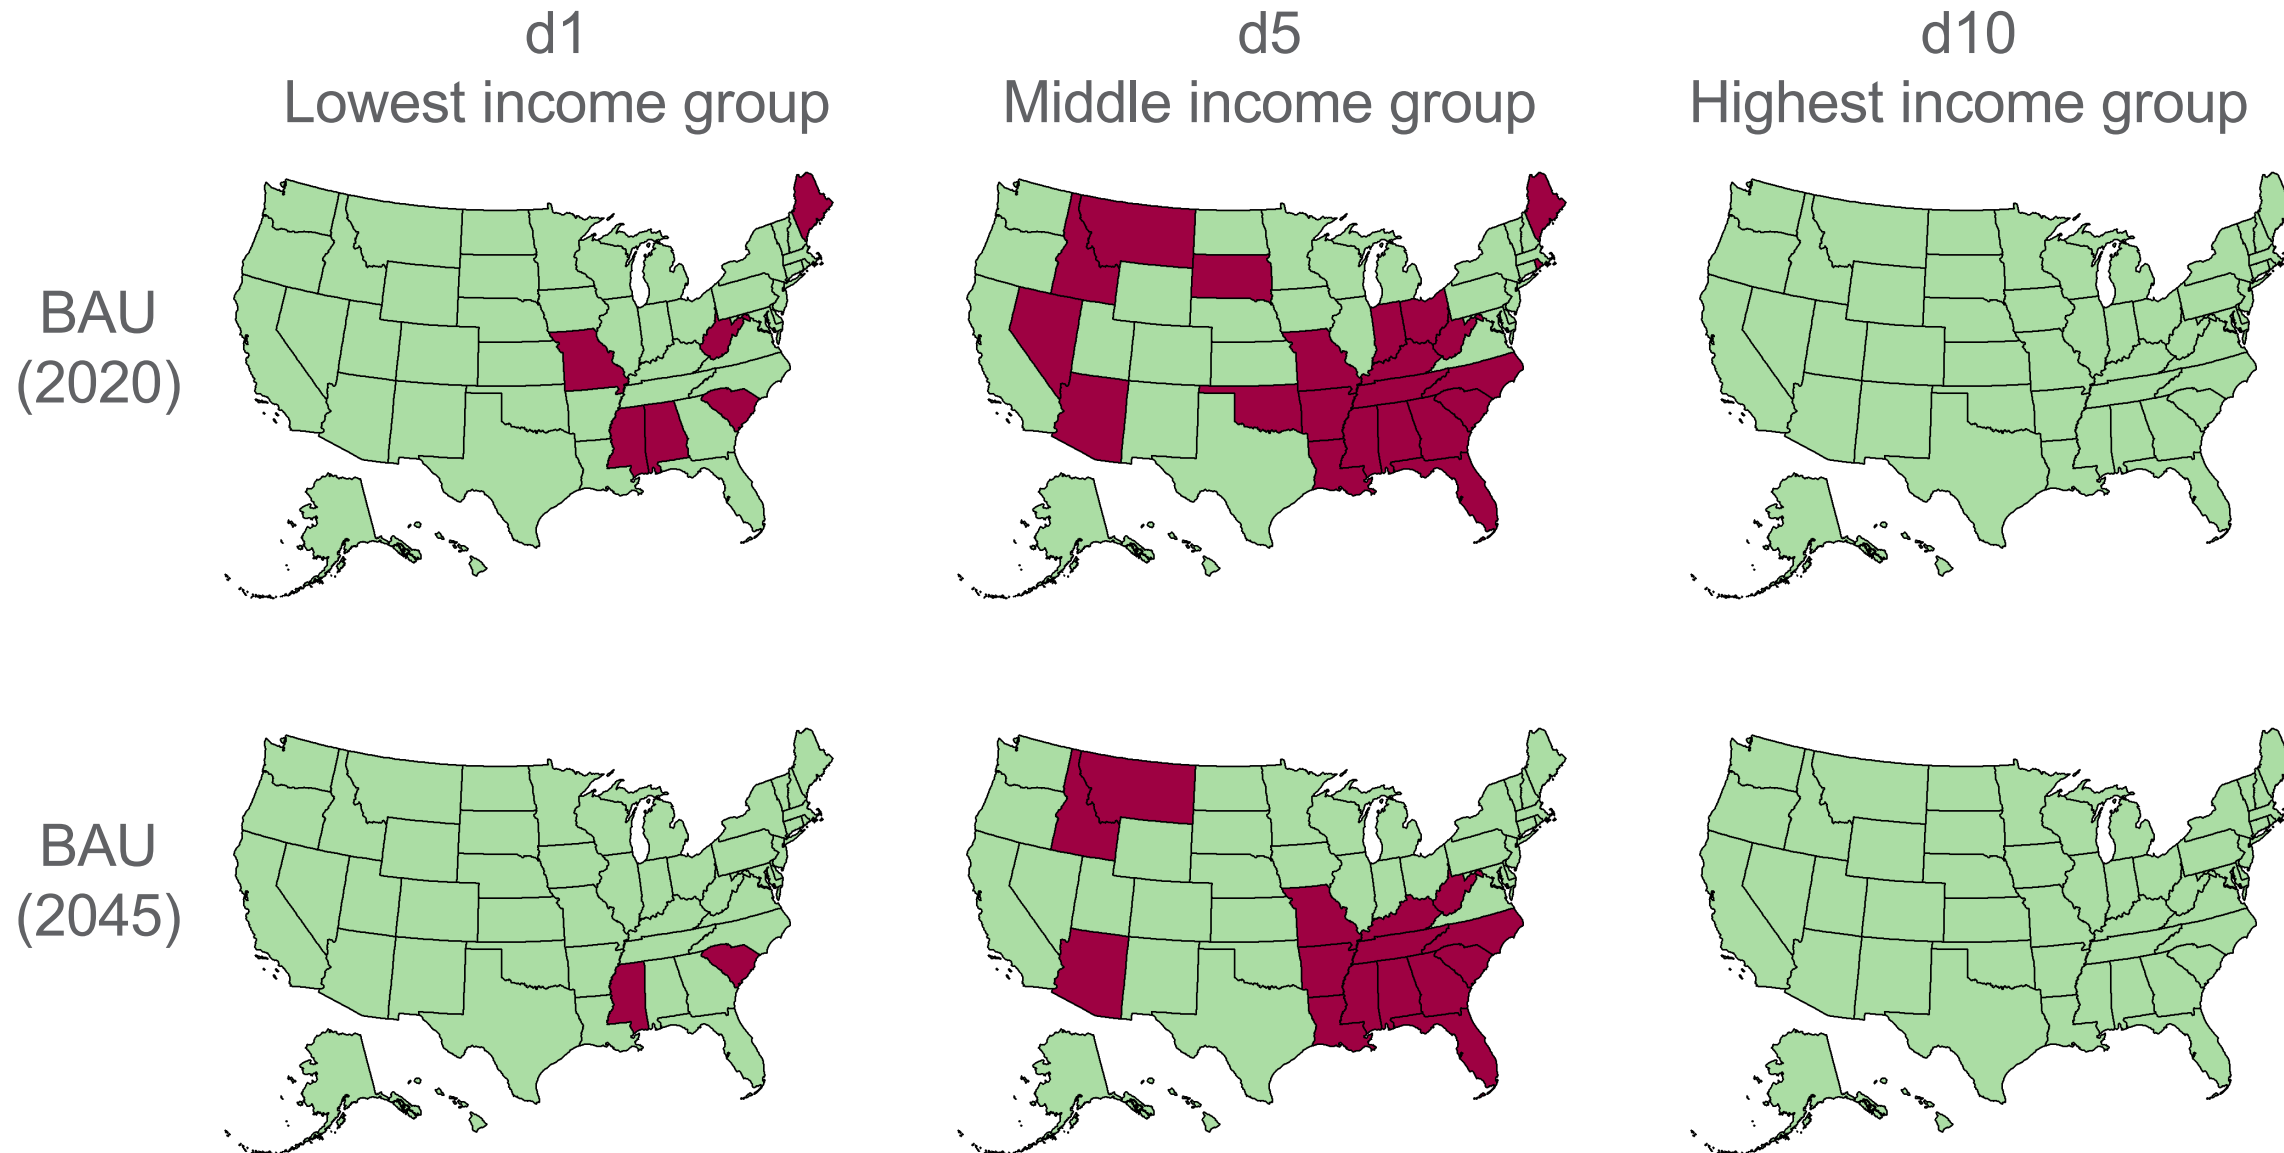

Impacts of a net-zero policy on residential modern heating service satiation gap in 2045

* Satiation Gap_{i,j,k} = (satiation level_{j,k} - service output_{i,j,k}) / satiation level_{j,k} for income group *i* and service *j* in state *k*. Note that the satiation level and service output are per unit of floorspace.

Residential energy burden under Business as Usual

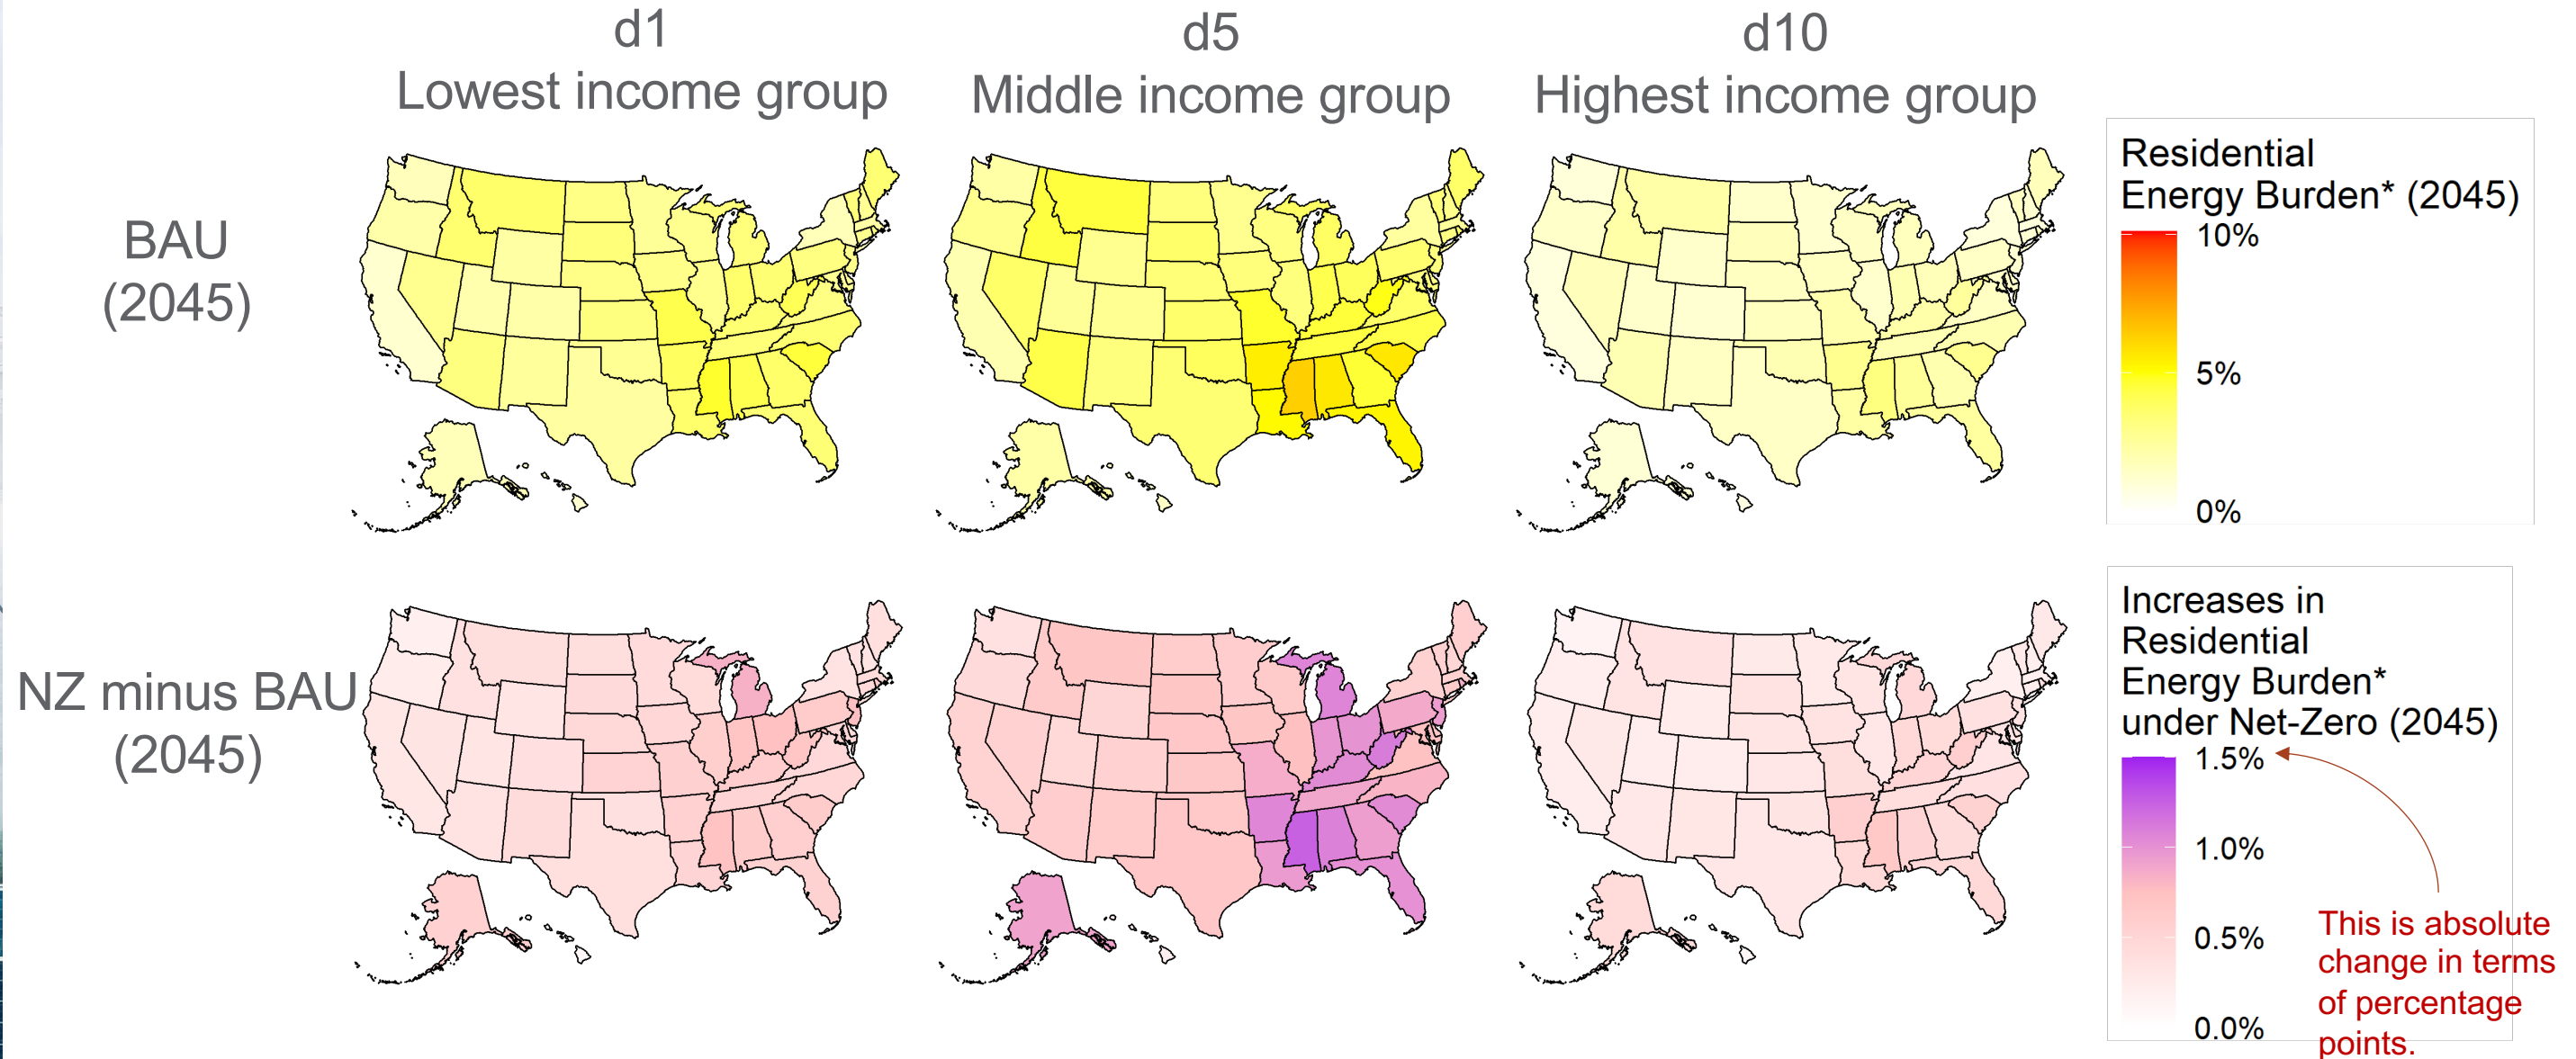

“Percentage of household income that is spent on residential energy services.”

Threshold defined based on U.S. EIA report, such that in 2020, roughly 27% of the U.S. total population fell into the “High” energy burden category.

Impacts of a net-zero policy on residential energy burden in 2045

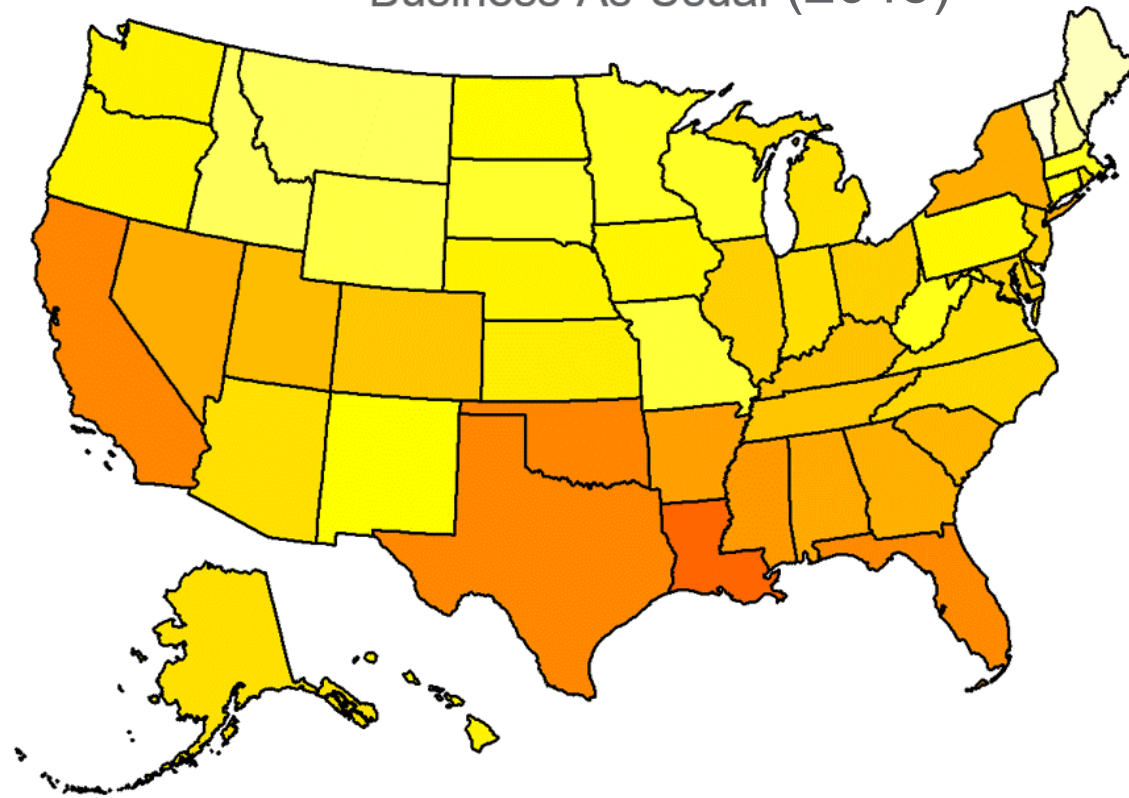

$$* \text{Energy burden}_{i,k} = \frac{\sum_j (\text{service output}_{i,j,k} * \text{service cost}_{j,k})}{\text{GDP}_{i,k}}$$

for income group i and service j in state k . Note that the service output here is the total service output in state k .

Residential heating service inequality in 2045

Business-As-Usual (2045)

Residential Heating Service Inequality* (2045)

The service inequality is similar to the Palma ratio, which is often used for measuring income inequality. **A higher Palma ratio indicates a greater degree of inequality.**

$$* \text{Service Inequality}_{j,k} = \frac{S_{j,k}^{d10}}{(S_{j,k}^{d1} + S_{j,k}^{d2} + S_{j,k}^{d3} + S_{j,k}^{d4})}$$

where S is the residential service output *per capita* for service j in state k

Key messages

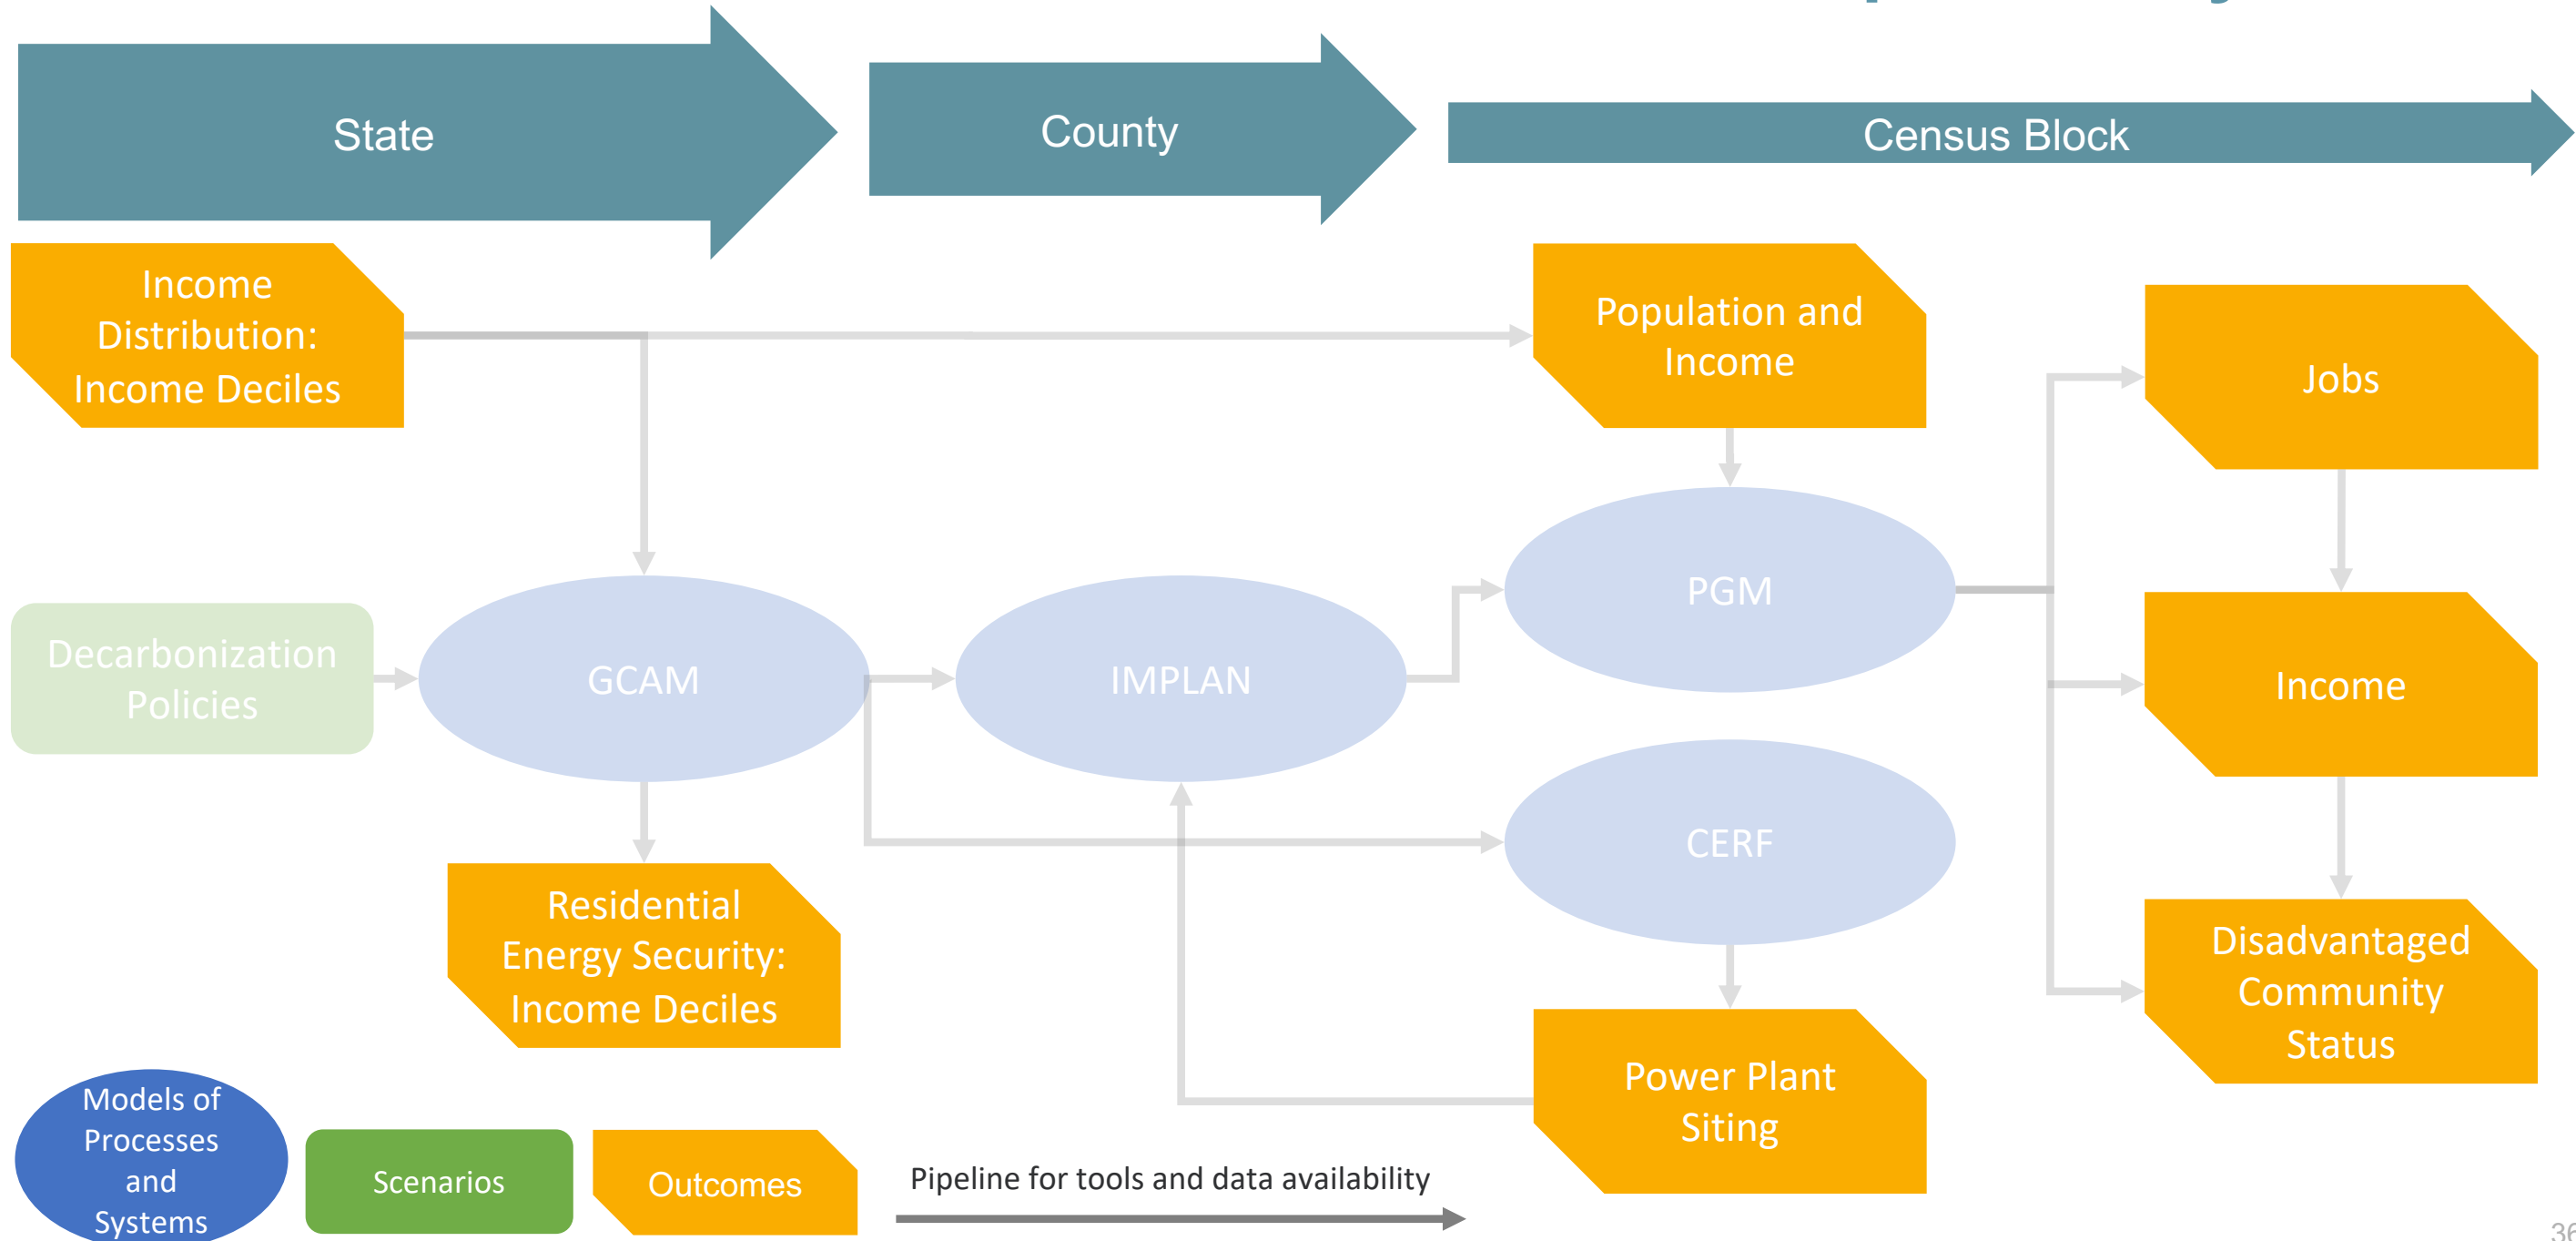

- Our research analyzes and quantifies decarbonization impacts on residential energy security across different income groups and states
- Despite the influence of decarbonization policies, income disparity remains a significant factor affecting residential energy security
- The impacts of decarbonization policies on residential energy security vary across income groups
- The decarbonization policy scenario exacerbates existing disparities in energy services among income groups
- This research can help make informed decisions when it comes to designing equitable decarbonization policies.

Results presented are available at Zenodo –
Zhang, Ying, Waldhoff, Stephanie, Ou, Yang, & Iyer, Gokul. (2023). Projecting Residential Energy Consumption across Multiple Income Groups under Decarbonization Scenarios using GCAM-USA (v1.0.0) [Data set]. Zenodo. <https://doi.org/10.5281/zenodo.7988038>
